The Altera® floating-point megafunction IP cores enable you to perform floating-point arithmetic in FPGAs through optimized parameterizable functions for Altera device architectures.

You can customize the IP cores by configuring various parameters to accommodate your needs.

List of Floating-Point IP Cores

This table lists the Floating-Point IP cores.

Table 1-1: List of IP Cores

IP Core Name	Function Overview
Operator Functions	
ALTFP_ADD_SUB	Adder/Subtractor
ALTFP_DIV	Divider
ALTFP_MULT	Multiplier
ALTFP_SQRT	Square Root
Algebraic and Trancendental Functions	
ALTFP_EXP	Exponential
ALTFP_INV	Inverse
ALTFP_INV_SQRT	Inverse Square Root
ALTFP_LOG	Natural Logarithm
Trigonometric Functions	
ALTFP_ATAN	Arctangent
ALTFP_SINCOS	Trigonometric Sine/Cosine
Other Functions	
ALTFP_ABS	Absolute value
ALTFP_COMPARE	Comparator
ALTFP_CONVERT	Converter

Provides general information about Altera IP cores

Installing and Licensing IP Cores

The Altera IP Library provides many useful IP core functions for your production use without purchasing an additional license. Some Altera MegaCore[®] IP functions require that you purchase a separate license for production use. However, the OpenCore[®] feature allows evaluation of any Altera[®] IP core in simulation and compilation in the software. After you are satisfied with functionality and performance, visit the Self Service Licensing Center to obtain a license number for any Altera product.

Figure 1-1: IP Core Installation Path

Note: The default IP installation directory on Windows is `<drive>:\altera\<version number>`; on Linux it is `<home directory>/altera/ <version number>`.

Design Flow

Use the IP Catalog and parameter editor to define and instantiate complex IP cores. Using the GUI ensures that you set all IP core ports and parameters properly.

If you are an expert user, and choose to configure the IP core directly through parameterized instantiation in your design, refer to the port and parameter details. The details of these ports and parameters are hidden in the parameter editor.

IP Catalog and Parameter Editor

The IP Catalog (**Tools > IP Catalog**) and parameter editor help you easily customize and integrate IP cores into your project. You can use the IP Catalog and parameter editor to select, customize, and generate files representing your custom IP variation.

Note: The IP Catalog (**Tools > IP Catalog**) and parameter editor replace the MegaWizard™ Plug-In Manager for IP selection and parameterization, beginning in software version 14.0. Use the IP Catalog and parameter editor to locate and parameterize Altera IP cores.

The IP Catalog lists installed IP cores available for your design. Double-click any IP core to launch the parameter editor and generate files representing your IP variation. The parameter editor prompts you to specify an IP variation name, optional ports, and output file generation options. The parameter editor generates a top-level Qsys system file (**.qsys**) or IP file (**.qip**) representing the IP core in your project. You can also parameterize an IP variation without an open project.

Use the following features to help you quickly locate and select an IP core:

- Filter IP Catalog to **Show IP for active device family** or **Show IP for all device families**. If you have no project open, select the **Device Family** in IP Catalog.
- Type in the Search field to locate any full or partial IP core name in IP Catalog.
- Right-click an IP core name in IP Catalog to display details about supported devices, open the IP core's installation folder, and view links to documentation.
- Click **Search for Partner IP**, to access partner IP information on the Altera website.

Figure 1-2: IP Catalog

Note: The IP Catalog is also available in Qsys (**View > IP Catalog**). The Qsys IP Catalog includes exclusive system interconnect, video and image processing, and other system-level IP that are not available in the IP Catalog. For more information about using the Qsys IP Catalog, refer to *Creating a System with Qsys* in the *Handbook*.

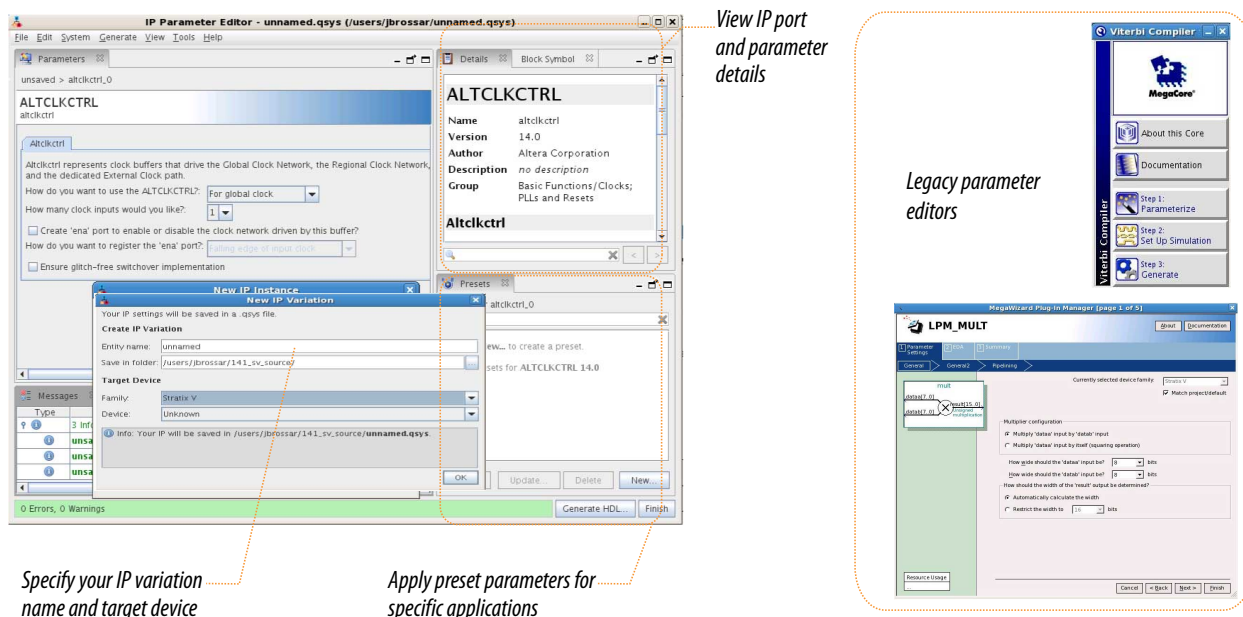

Using the Parameter Editor

The parameter editor helps you to configure IP core ports, parameters, and output file generation options.

- Use preset settings in the parameter editor (where provided) to instantly apply preset parameter values for specific applications.
- View port and parameter descriptions, and links to documentation.
- Generate testbench systems or example designs (where provided).

Figure 1-3: IP Parameter Editors

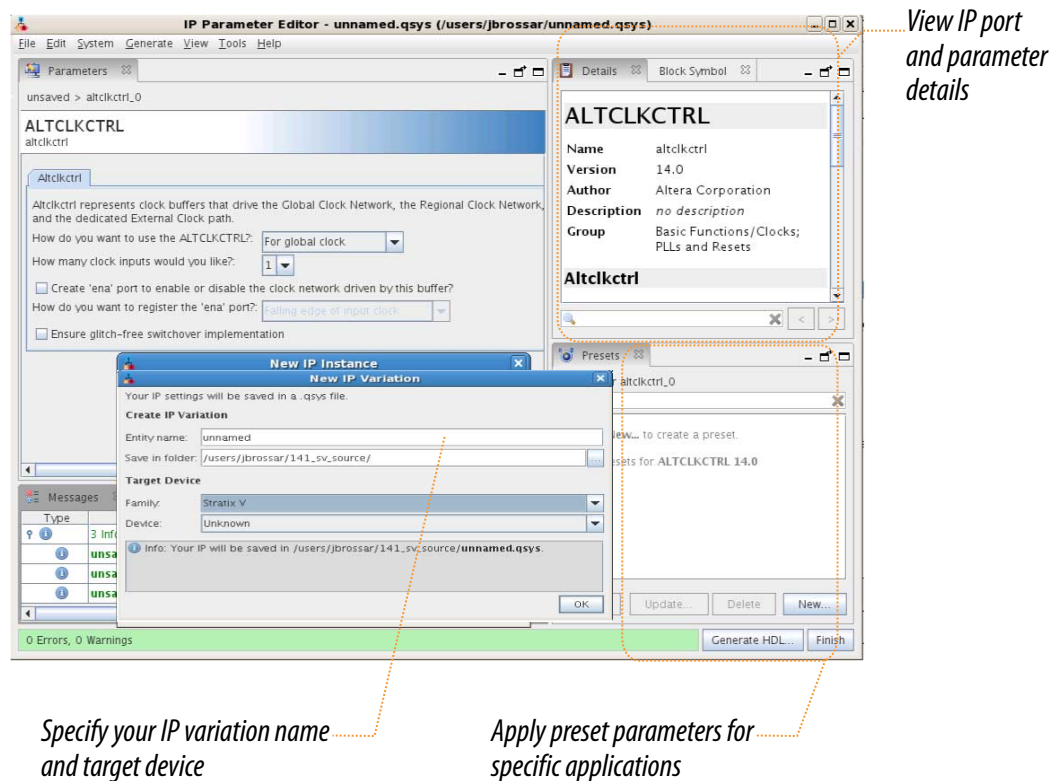

Specifying IP Core Parameters and Options

You can quickly configure a custom IP variation in the parameter editor. Use the following steps to specify IP core options and parameters in the parameter editor. Refer to *Specifying IP Core Parameters and Options (Legacy Parameter Editors)* for configuration of IP cores using the legacy parameter editor.

1. In the IP Catalog (**Tools > IP Catalog**), locate and double-click the name of the IP core to customize. The parameter editor appears.
2. Specify a top-level name for your custom IP variation. The parameter editor saves the IP variation settings in a file named *<your_ip>.qsys*. Click **OK**.
3. Specify the parameters and options for your IP variation in the parameter editor, including one or more of the following. Refer to your IP core user guide for information about specific IP core parameters.
 - Optionally select preset parameter values if provided for your IP core. Presets specify initial parameter values for specific applications.
 - Specify parameters defining the IP core functionality, port configurations, and device-specific features.
 - Specify options for processing the IP core files in other EDA tools.
4. Click **Generate HDL**, the **Generation** dialog box appears.
5. Specify output file generation options, and then click **Generate**. The IP variation files generate according to your specifications.
6. To generate a simulation testbench, click **Generate > Generate Testbench System**.

7. To generate an HDL instantiation template that you can copy and paste into your text editor, click **Generate > HDL Example**.
8. Click **Finish**. The parameter editor adds the top-level **.qsys** file to the current project automatically. If you are prompted to manually add the **.qsys** file to the project, click **Project > Add/Remove Files in Project** to add the file.
9. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.

Figure 1-4: IP Parameter Editor

Files Generated for Altera IP Cores and Qsys Systems

The Quartus Prime software generates the following output file structure for IP cores and Qsys systems.

Figure 1-5: Files generated for IP cores and Qsys Systems

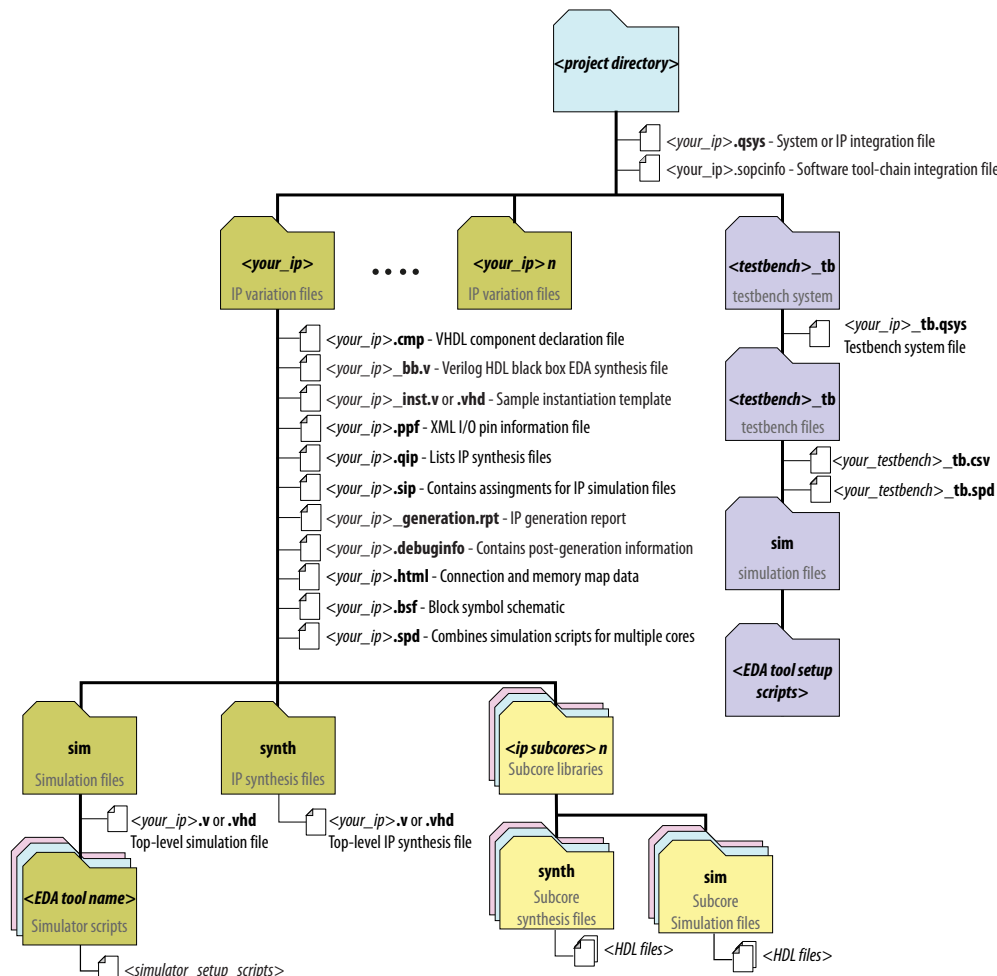

Table 1-2: IP Core and Qsys Simulation Generated Files

File Name	Description
<my_ip>.qsys	The Qsys system or top-level IP variation file. <my_ip> is the name that you give your IP variation. You must add the .qsys file to your Quartus project to enable NativeLink for Arria 10 and Stratix 10 device families.
<system>.sopcinfo	Describes the connections and IP component parameterizations in your Qsys system. You can parse its contents to get requirements when you develop software drivers for IP components. Downstream tools such as the Nios II tool chain use this file. The .sopcinfo file and the system.h file generated for the Nios II tool chain include address map information for each slave relative to each master that accesses the slave. Different masters may have a different address map to access a particular slave component.

File Name	Description
<my_ip>.cmp	The VHDL Component Declaration (.cmp) file is a text file that contains local generic and port definitions that you can use in VHDL design files.
<my_ip>.html	A report that contains connection information, a memory map showing the address of each slave with respect to each master to which it is connected, and parameter assignments.
<my_ip>_generation.rpt	IP or Qsys generation log file. A summary of the messages during IP generation.
<my_ip>.debuginfo	Contains post-generation information. Used to pass System Console and Bus Analyzer Toolkit information about the Qsys interconnect. The Bus Analysis Toolkit uses this file to identify debug components in the Qsys interconnect.
<my_ip>.qip	Contains all the required information about the IP component to integrate and compile the IP component in the software.
<my_ip>.csv	Contains information about the upgrade status of the IP component.
<my_ip>.bsf	A Block Symbol File (.bsf) representation of the IP variation for use in Block Diagram Files (.bdf).
<my_ip>.spd	Required input file for <code>ip-make-simscript</code> to generate simulation scripts for supported simulators. The .spd file contains a list of files generated for simulation, along with information about memories that you can initialize.
<my_ip>.ppf	The Pin Planner File (.ppf) stores the port and node assignments for IP components created for use with the Pin Planner.
<my_ip>_bb.v	You can use the Verilog black-box (_bb.v) file as an empty module declaration for use as a black box.
<my_ip>.sip	Contains information required for NativeLink simulation of IP components. You must add the .sip file to your Quartus project to enable NativeLink for Arria II, Arria V, Cyclone IV, Cyclone V, MAX 10, MAX II, MAX V, Stratix IV, and Stratix V devices.
<my_ip>_inst.v or _inst.vhd	HDL example instantiation template. You can copy and paste the contents of this file into your HDL file to instantiate the IP variation.
<my_ip>.regmap	If the IP contains register information, the .regmap file generates. The .regmap file describes the register map information of master and slave interfaces. This file complements the .sopcinfo file by providing more detailed register information about the system. This enables register display views and user customizable statistics in System Console.

File Name	Description
<my_ip>.svd	Allows HPS System Debug tools to view the register maps of peripherals connected to HPS within a Qsys system. During synthesis, the .svd files for slave interfaces visible to System Console masters are stored in the .sof file in the debug section. System Console reads this section, which Qsys can query for register map information. For system slaves, Qsys can access the registers by name.
<my_ip>.v or <my_ip>.vhd	HDL files that instantiate each submodule or child IP core for synthesis or simulation.
mentor/	Contains a ModelSim® script msim_setup.tcl to set up and run a simulation.
aldec/	Contains a Riviera-PRO script rivierapro_setup.tcl to setup and run a simulation.
/synopsys/vcs /synopsys/vcsmx	Contains a shell script vcs_setup.sh to set up and run a VCS® simulation. Contains a shell script vcsmx_setup.sh and synopsys_sim.setup file to set up and run a VCS MX® simulation.
/cadence	Contains a shell script ncsim_setup.sh and other setup files to set up and run an NCSIM simulation.
/submodules	Contains HDL files for the IP core submodule.
<child IP cores>/	For each generated child IP core directory, Qsys generates /synth and /sim sub-directories.

Note: For information about output file structures for legacy IP cores, refer to *Introduction to IP Altera Cores*.

Related Information

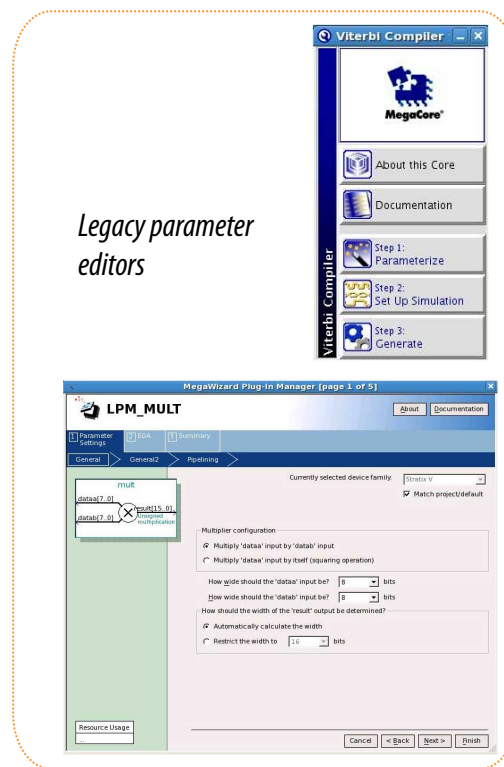

- [Introduction to Altera IP Cores](#)

Specifying IP Core Parameters and Options (Legacy Parameter Editors)

Some IP cores use a legacy version of the parameter editor for configuration and generation. Use the following steps to configure and generate an IP variation using a legacy parameter editor.

Note: The legacy parameter editor generates a different output file structure than the latest parameter editor. Refer to *Specifying IP Core Parameters and Options* for configuration of IP cores that use the latest parameter editor.

Figure 1-6: Legacy Parameter Editors

1. In the IP Catalog (**Tools > IP Catalog**), locate and double-click the name of the IP core to customize. The parameter editor appears.
2. Specify a top-level name and output HDL file type for your IP variation. This name identifies the IP core variation files in your project. Click **OK**.
3. Specify the parameters and options for your IP variation in the parameter editor. Refer to your IP core user guide for information about specific IP core parameters.
4. Click **Finish** or **Generate** (depending on the parameter editor version). The parameter editor generates the files for your IP variation according to your specifications. Click **Exit** if prompted when generation is complete. The parameter editor adds the top-level **.qip** file to the current project automatically.

Note: To manually add an IP variation generated with legacy parameter editor to a project, click **Project > Add/Remove Files in Project** and add the IP variation **.qip** file.

Upgrading IP Cores

IP core variants generated with a previous version of the software may require upgrading before use in the current version of the software. Click **Project > Upgrade IP Components** to identify and upgrade outdated IP core variants.

Icons in the **Upgrade IP Components** dialog box indicate when IP upgrade is required, optional, or unsupported for IP cores in your design. This dialog box may open automatically when you open a project containing upgradeable IP variations. You must upgrade IP cores that require upgrade before you can compile the IP variation in the current version of the software.

The upgrade process preserves the original IP variation file in the project directory as `<my_variant>_BAK.qsys` for IP targeting Arria 10 and later devices, and as `<my_variant>_BAK.v`, `.sv`, or `.vhd` for legacy IP targeting 28nm devices and greater.

Note: Upgrading IP cores for Arria 10 and later devices may append a unique identifier to the original IP core entity name(s), without similarly modifying the IP instance name. There is no requirement to update these entity references in any supporting file; such as the Settings File (`.qsf`), Synopsys Design Constraints File (`.sdc`), or SignalTap File (`.stp`), if these files contain instance names. The software reads only the instance name and ignores the entity name in paths that specify both names. Use only instance names in assignments.

Table 1-3: IP Core Upgrade Status

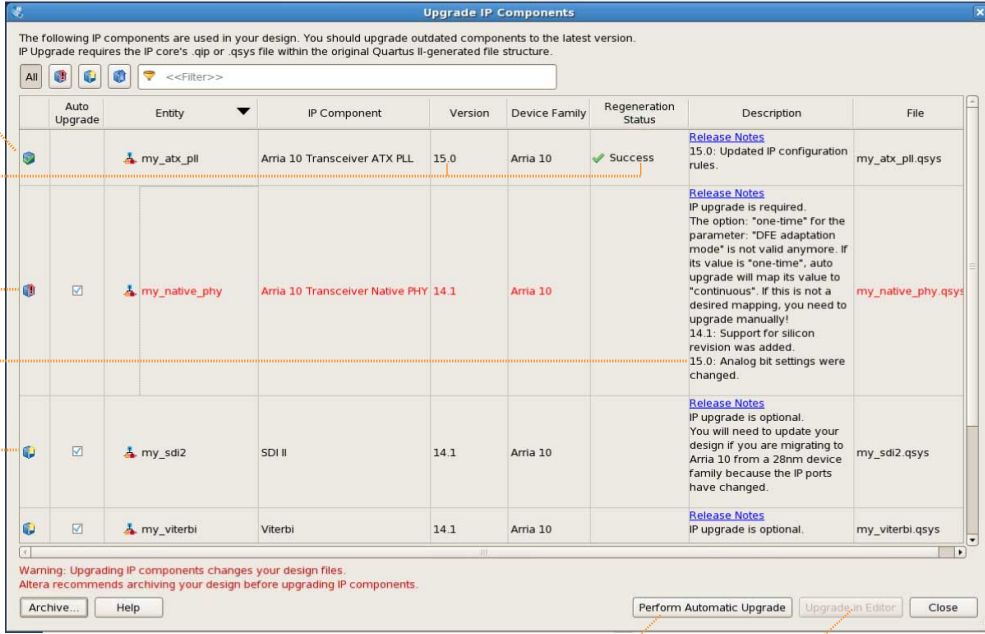

IP Core Status	Description
IP Upgraded 	Your IP variation uses the latest version of the IP core.
IP Upgrade Optional 	Upgrade is optional for this IP variation in the current version of the software. You can upgrade this IP variation to take advantage of the latest development of this IP core. Alternatively you can retain previous IP core characteristics by declining to upgrade. Refer to the Description for details about IP core version differences. If you do not upgrade the IP, the IP variation synthesis and simulation files are unchanged and you cannot modify parameters until upgrading.
IP Upgrade Mismatch Warning 	Warning of non-critical IP core differences in migrating IP to another device family.
IP Upgrade Required 	You must upgrade the IP variation before compiling in the current version of the software. Refer to the Description for details about IP core version differences.
IP Upgrade Unnsported 	Upgrade of the IP variation is not supported in the current version of the software due to incompatibility with the current version of the software. You are prompted to replace the unsupported IP core with a supported equivalent IP core from the IP Catalog. Refer to the Description for details about IP core version differences and links to Release Notes.
IP End of Life 	Altera designates the IP core as end-of-life status. You may or may not be able to edit the IP core in the parameter editor. Support for this IP core discontinues in future releases of the software.

IP Core Status	Description
Encrypted IP Core 	The IP variation is encrypted.

Follow these steps to upgrade IP cores:

1. In the latest version of the software, open the project containing an outdated IP core variation. The **Upgrade IP Components** dialog automatically displays the status of IP cores in your project, along with instructions for upgrading each core. Click **Project > Upgrade IP Components** to access this dialog box manually.
2. To upgrade one or more IP cores that support automatic upgrade, ensure that the **Auto Upgrade** option is turned on for the IP core(s), and then click **Perform Automatic Upgrade**. The **Status** and **Version** columns update when upgrade is complete. Example designs provided with any Altera IP core regenerate automatically whenever you upgrade an IP core.
3. To manually upgrade an individual IP core, select the IP core and then click **Upgrade in Editor** (or simply double-click the IP core name). The parameter editor opens, allowing you to adjust parameters and regenerate the latest version of the IP core.

Figure 1-7: Upgrading IP Cores

"Auto Upgrade" supported

"Auto Upgrade" successful

Upgrade required

Upgrade details

Upgrade optional

Runs "Auto Upgrade" on all supported outdated cores

Opens editor for manual IP upgrade

Note: IP cores older than software version 12.0 do not support upgrade. Altera verifies that the current version of the software compiles the previous version of each IP core. The *Altera IP Release Notes* reports any verification exceptions for Altera IP cores. Altera does not verify compilation for IP cores older than the previous two releases.

[Altera IP Release Notes](#)

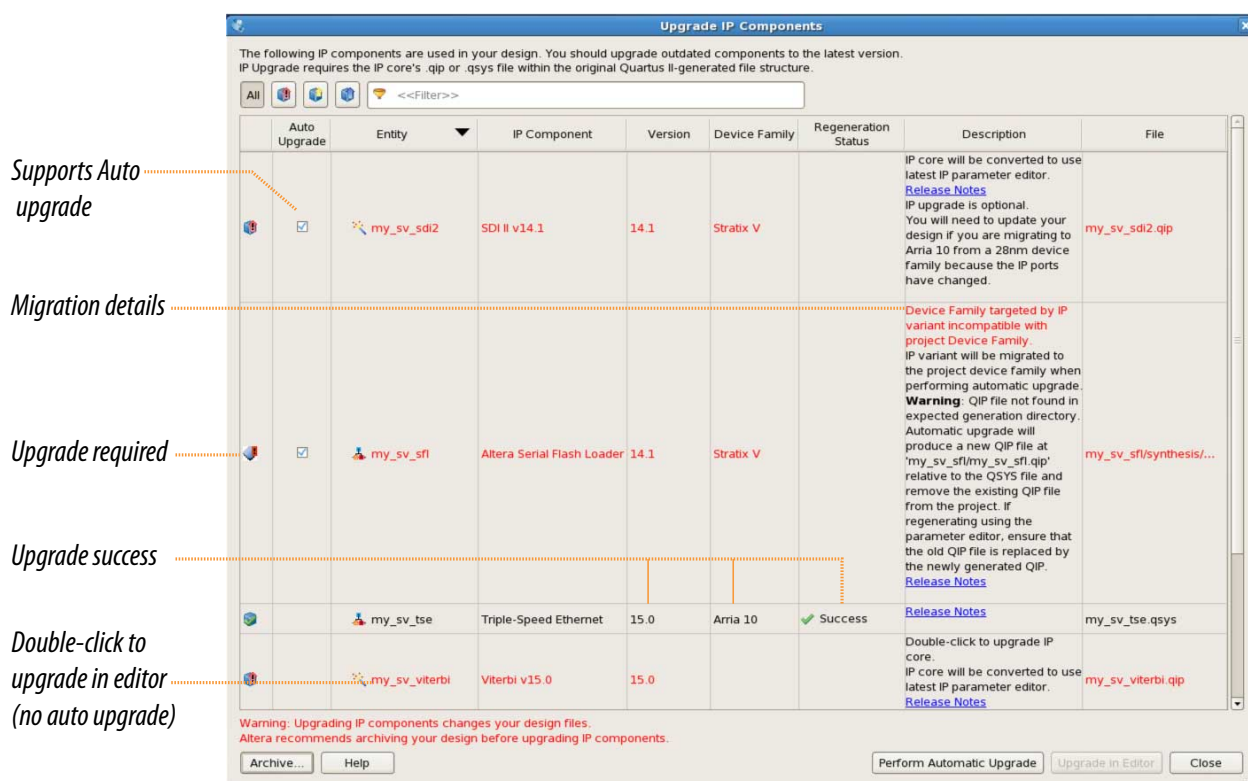

Migrating IP Cores to a Different Device

IP migration allows you to target the latest device families with IP originally generated for a different device. Some Altera IP cores migrate automatically, some IP cores require manual IP regeneration, and some do not support device migration and must be replaced in your design.

The text and icons in the **Upgrade IP Components** dialog box identifies the migration support for each IP core in the design.

Note: Migration of some IP cores requires installed support for the original and migration device families. For example, migration from a Stratix V device to an Arria 10 device requires installation of Stratix V and Arria 10 device families with the software.

Figure 1-8: Upgrading IP Cores

1. Click **File > Open Project** and open the project containing IP for migration to another device in the original version of the software.
2. To specify a different target device for migration, click **Assignments > Device** and select the target device family.
3. To display IP cores requiring migration, click **Project > Upgrade IP Components**. The **Description** field prompts you to run auto update or double-click IP cores for migration.
4. To migrate one or more IP cores that support automatic upgrade, ensure that the **Auto Upgrade** option is turned on for the IP core(s), and then click **Perform Automatic Upgrade**. The **Status** and **Version** columns update when upgrade is complete.

5. To migrate an IP core that does not support automatic upgrade, double-click the IP core name, and then click **OK**. The parameter editor appears.
 - a. If the parameter editor specifies a **Currently selected device family**, turn off **Match project/default**, and then select the new target device family.
 - b. Click **Finish** to migrate the IP variation using best-effort mapping to new parameters and settings. A new parameter editor opens displaying best-effort mapped parameters.
 - c. Click **Generate HDL**, and then confirm the **Synthesis** and **Simulation** file options. Verilog HDL is the default output file format specified. If your original IP core was generated for VHDL, select **VHDL** to retain the original output format.
6. To regenerate the new IP variation for the new target device, click **Generate**. When generation is complete, click **Close**.
7. Click **Finish** to complete migration of the IP core. Click **OK** if you are prompted to overwrite IP core files. The **Device Family** column displays the new target device name when migration is complete. The migration process replaces `<my_ip>.qip` with the `<my_ip>.qsys` top-level IP file in your project.

Note: If migration does not replace `<my_ip>.qip` with `<my_ip>.qsys`, click **Project > Add/Remove Files in Project** to replace the file in your project.

8. Review the latest parameters in the parameter editor or generated HDL for correctness. IP migration may change ports, parameters, or functionality of the IP core. During migration, the IP core's HDL generates into a library that is different from the original output location of the IP core. Update any assignments that reference outdated locations. If your upgraded IP core is represented by a symbol in a supporting Block Design File schematic, replace the symbol with the newly generated `<my_ip>.bsf` after migration.

Note: The migration process may change the IP variation interface, parameters, and functionality. This may require you to change your design or to re-parameterize your variant after the **Upgrade IP Components** dialog box indicates that migration is complete. The **Description** field identifies IP cores that require design or parameter changes.

[Altera IP Release Notes](#)

Floating-Point IP Cores General Features

All Altera floating-point IP cores offer the following features:

- Support for floating-point formats.
- Input support for not-a-number (NaN), infinity, zero, and normal numbers.
- Optional asynchronous input ports including asynchronous clear (`aclr`) and clock enable (`clk_en`).
- Support for round-to-nearest-even rounding mode.
- Compute results of any mathematical operations according to the IEEE-754 standard compliance with a maximum of 1 unit in the last place (u.l.p.) error. This assumption is applied to all floating-point IP cores excluding complex matrix multiplication and inverse operations (for example, `ALTFP_MATRIX_MULTI` and `ALFP_MATRIX_INV`), where a slight increase in errors is observed due to the accumulation of errors during the mathematical operation.

Altera floating-point IP cores do not support denormal number inputs. If the input is a denormal value, the IP core forces the value to zero and treats the value as a zero before going through any operation.

Related Information**FFT MegaCore Function User Guide**

Altera also offers the single-precision floating-point option in the FFT MegaCore.

IEEE-754 Standard for Floating-Point Arithmetic

The floating-point IP cores implement the following representations in the IEEE-754 standard:

- Floating-point numbers
- Special values (zero, infinity, denormal numbers, and NaN bit combinations)
- Single-precision, double-precision, and single-extended precision formats for floating-point numbers

Floating-Point Formats

All floating-point formats have binary patterns. In Figure 1–1, S represents a sign bit, E represents an exponent field, and M is the mantissa (part of a logarithm, or fraction) field.

For a normal floating-point number, a leading 1 is always implied, for example, binary 1.0011 or decimal 1.1875 is stored as 0011 in the mantissa field. This format saves the mantissa field from using an extra bit to represent the leading 1. However, the leading bit for a denormal number can be either 0 or 1. For zero, infinity, and NaN, the mantissa field does not have an implied leading 1 nor any explicit leading bit.

Figure 1-9: IEEE-754 Floating-Point Format

This figure shows a floating-point format.

Single-Precision Format

The single-precision format contains the following binary patterns:

- The MSB holds the sign bit.
- The next 8 bits hold the exponent bits.
- 23 LSBs hold the mantissa.

The total width of a floating-point number in the single-precision format is 32 bits. The bias for the single-precision format is 127.

Figure 1-10: Single-Precision Representation

This figure shows a single-precision representation.

Double-Precision Format

The double-precision format contains the following binary patterns:

- The MSB holds the sign bit.
- The next 11 bits hold the exponent bits.
- 52 LSBs hold the mantissa.

The total width of a floating-point number in the double-precision format is 64 bits. The bias for the double-precision format is 1023.

Figure 1-11: Double-Precision Representation

This figure shows a double-precision representation.

Single-Extended Precision Format

The single-extended precision format contains the following binary patterns:

- The MSB holds the sign bit.
- The exponent and mantissa fields do not have fixed widths.
- The minimum exponent field width is 11 bits and must be less than the width of the mantissa field.
- The width of the mantissa field must be a minimum of 31 bits.

The sum of the widths of the sign bit, exponent field, and mantissa field must be a minimum of 43 bits and a maximum of 64 bits. The bias for the single-extended precision format is unspecified in the IEEE-754 standard. In these IP cores, a bias of $2^{(\text{WIDTH_EXP}-1)}-1$ is assumed for the single-extended precision format.

Special Case Numbers

The following table lists the special case numbers defined by the IEEE-754 standard and the data bit representations.

Table 1-4: Special Case Numbers in IEEE-754 Representation

Meaning	Sign Field	Exponent Field	Mantissa Field
Zero	Don't care	All 0's	All 0's
Positive Denormalized	0	All 0's	Non-zero
Negative Denormalized	1	All 0's	Non-zero
Positive Infinity	0	All 1's	All 0's
Negative Infinity	1	All 1's	All 0's
Not-a-Number (NaN)	Don't care	All 1's	Non-zero

Rounding

The IEEE-754 standard defines four types of rounding modes, which are:

- round-to-nearest-even
- round-toward-zero
- round-toward-positive-infinity
- round-toward-negative-infinity

Altera floating-point IP cores support only the most commonly used rounding mode, which is the round-to-nearest-even mode (`TO_NEAREST`). With round-to-nearest-even, the IP core rounds the result to the nearest floating-point number. If the result is exactly halfway between two floating-point numbers, the IP core rounds the result so that the LSB becomes a zero, which is even.

Non-IEEE-754 Standard Format

Only the `ALTFP_CONVERT` and `ALTERA_FP_FUNCTIONS` (when the convert function is selected) support the fixed point format.

The fixed-point data type is similar to the conventional integer data type, except that the fixed-point data carries a predetermined number of fractional bits. If the width of the fraction is 0, the data becomes a normal signed integer.

The notation for fixed-point format numbers in this user guide is $Q_m.f$, where Q designates that the number is in Q format notation, m is the number of bits used to indicate the integer portion of the number, and f is the number of bits used to indicate the fractional portion of the number.

For example, $Q_{4.12}$ describes a number with 4 integer bits and 12 fractional bits in a 16-bit word.

The following figures show the difference between the signed-integer format and the fixed-point format for a 32-bit number.

Figure 1-12: Signed-Integer Format

Figure 1-13: Fixed-Point Format

Floating-Points IP Cores Output Latency

The IP cores measure the output latency in clock cycles and is different for each IP core. In some IP cores, the precision modes determine the number of clock cycles between the input and output result. When you select a mode, the options for latency are fixed for that mode.

For specific details about latency options, refer to the Output *Latency* section of your selected IP core in this user guide.

Floating-Point IP Cores Design Example Files

The design examples for each IP core in this user guide use the IP Catalog and parameter editor to define custom IP variations.

Simulate the designs in the ModelSim®-Altera software to generate a waveform display of the device behavior. You must be familiar with the ModelSim-Altera software before trying out the design examples.

ALTERA_FP_MATRIX_INV Features

The ALTERA_FP_MATRIX_INV IP core offers the following features:

- Inversion of a matrix.
- Support for floating-point format in single precision.
- Support for VHDL and Verilog HDL languages.
- Support for matrix sizes up to are 4×4 , 6×6 , 8×8 , 16×16 , 32×32 , and 64×64 .
- Use of control signal, `load`.
- Use of handshaking signals: `busy`, `outvalid`, and `done`.

ALTERA_FP_MATRIX_INV Output Latency

The ALTERA_FP_MATRIX_INV IP core does not have a fixed output latency. Instead, it uses handshaking signals to interface with external circuitry.

ALTERA_FP_MATRIX_INV Resource Utilization and Performance

This table lists the resource utilization and performance information for the ALTERA_FP_MATRIX_INV IP core. The information was derived using the Quartus II software version 10.0

ALTERA_FP_MATRIX_INV Functional Description

A matrix inversion function is composed of the following components:

- Cholesky decomposition function.

The Cholesky decomposition function generates a lower triangular matrix.

- Triangular matrix inversion function.

The triangular matrix inversion process then generates the inverse of the lower triangular using backward substitution.

- Matrix multiplication function.

The matrix multiplier multiplies the transpose of the inverse triangular matrix with the inverse triangular matrix.

In linear algebra, the Cholesky decomposition states that every positive definite matrix A is decomposed as $A = L \times L^T$

where, L is a lower triangular matrix, and L^T denotes the transpose of L.

The property of invertible matrices states that $(X \times Y)^{-1} = Y^{-1} \times X^{-1}$ and the property of transpose states that $(X^T)^{-1} = (X^{-1})^T$. Combining these two properties, the following equation represents a derivation of a matrix inversion using the Cholesky decomposition method:

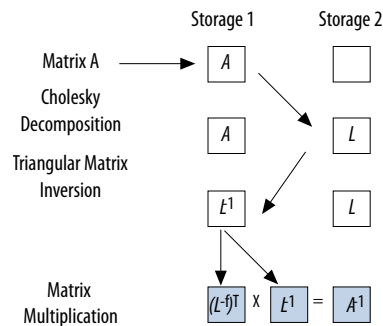

$$A^{-1} = (L \times L^T)^{-1}$$

$$= (L^T)^{-1} \times L^{-1}$$

$$= (L^{-1})^T \times L^{-1}$$

where a Cholesky decomposition function is needed to obtain L , a triangular matrix inversion is needed to obtain L^{-1} , and a matrix multiplication is needed for $(L^{-1})^T \times L^{-1}$.

Figure 2-1: Matrix Inversion Flow Diagram

Cholesky Decomposition Function

The function consists of two memory and two processing blocks. One of the memory blocks is the input matrix memory block and is loaded with the input matrix in a row order, one element at a time. However, during processing, this block is read in a column order, one element at a time when required.

The other memory block is the processing matrix block which consists of multiple column memories to enable an entire row to be read at once. During the loading of the input memory, the FPC datapath preprocesses the input elements to generate the first column of the resulting triangular matrix. The top element of the first column, l_{00} , is the square root of the input matrix value a_{00} . The rest of the first column, l_{i0} is the input value a_{i0} divided by l_{00} . This preprocessing step introduces latency into the load, during which the `INIT_BUSY` signal is asserted. The `CALCULATE` signal initiates and starts processing after the `INIT_BUSY` signal is deasserted.

This figure shows the top-level architecture of the Cholesky decomposition function, where the monolithic input memory and the column-wise processing memory, also known as the vector matrix, are shown. The grey block is the FPC datapath section.

Figure 2-2: Cholesky Decomposition Function Top-level Diagram

Although the Cholesky decomposition algorithm only operates on the lower triangular matrix, the core requires the entire matrix to be loaded, during which the processing or vector memory is initialized.

The FPC datapath is split into two sections. The first section, also known as the vector section, takes the inner product of two vectors and subtracts it from the input matrix element, a_{ij} . The second section, also known as the root section, calculates square roots and performs division by the square root. The first element is loaded into both inputs of the root section and the outcome is its own square root. The first element continues to stay latched in the left input field of the root section while all the other elements of the first column are loaded into the right input field. The resulting output is the value of the respective column element divided by the value of the first element of the Cholesky decomposition matrix.

During processing, two rows from the processing matrix are loaded. For the first element in each new column, both rows have the same index; hence contain the same values. The first row is latched into the input register of the vector section. For the rest of the column, the row index is increased, and a new a_{ij} element and triangular matrix vector, L_j is loaded. The first result out of the vector section is latched onto the left register of the root section. All results from the column, including the first result, are loaded into the right register of the root section. The root section generates the square root of the first vector result, while for the other results coming from the vector section, the number is divided by the square root of the first result.

All calculated values are written to another memory block for further processing. The first column values are output singly during preprocessing, while the values of other columns are burst out during processing.

There are only minor differences between the architectures for real and complex matrices. For the complex matrix, both the input and processing memory blocks contain complex values. Similarly, all values going into the vector section are complex numbers. The complex conjugate of the latched register is obtained by simply inverting the sign bit. As for the root section, the structure is simplified by the nature of the positive definite matrix. The diagonal value, which is the first value at the top of each column in the decomposition, is always a real number so that the result from the inverse square root calculation is always a real number. The complex multiplier in the root section is therefore a real scalar, so only two real multipliers are required.

Triangular Matrix Inversion

The triangular matrix, L , obtained from the Cholesky decomposition function is computed using the triangular matrix inversion algorithm to get its inversion. The following MatLab pseudo code shows how the inversion is carried out:

```
for j = n:-1:1,
X(j,j) = 1/L(j, j);
for k = j+1:n
for i = j+1:n
X(k, j) = X(k, j) + X(k, i)*L(i, j);
end;
end;
for k = j+1:n
X(k, j) = -X(j, j)*X(k, j);
end;
```

The pseudo code is converted into an RTL file. The result, L^{-1} is stored in the input matrix storage in the Cholesky decomposition function.

Matrix Multiplication

The final stage of the matrix inversion process involves multiplying the transpose of the inverse triangular matrix with the inverse triangular matrix using the Altera Floating-Point Matrix Multiplier. The original version of the matrix multiplier is modified for this purpose. As there are memory blocks already available for the storage of the input matrices in the Cholesky decomposition function, the memory blocks in the matrix multiplier are redundant and can be removed. Data is instead fed directly from the results stored at the end stage of the triangular matrix inversion algorithm.

Matrix Inversion Operation

Figure 2-3: Matrix Inversion Timing Diagram

The following sequence describes the matrix inversion operation:

1. The operation begins when the `enable` signal is asserted and the `reset` signal is deasserted.
2. The `load` signal is asserted to load data from the `loaddata[]` port for the input matrix. As long as the `load` signal is high, data is loaded continuously for the input matrix.
3. The `busy` signal is asserted and the `done` signal is deasserted for a few clock cycles after the `datain[]` signal is asserted.
4. The `outvalid` signal is asserted multiple times to signify the availability of valid data on the `dataout[]` port. The number of times this signal is asserted equals the number of rows found in the output matrix.
5. The `busy` and `done` signals are asserted when the last row of the output matrix has been burst out. This assertion signifies the end of the matrix inversion operation on the first set of data.

ALTERA_FP_MATRIX_INV Design Example: Matrix Inverse of Single-Precision Format Numbers

This design example uses the ALTERA_FP_MATRIX_INV IP core to show the matrix inversion operation. The input matrix applied is an 8×8 matrix with a block size of 2. This example uses the parameter editor GUI to define the core.

ALTERA_FP_MATRIX_INV Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

Figure 2-4: ALTERA_FP_MATRIX_INV ModelSim Simulation Waveform (Input Data)

This figure shows the expected simulation results in the ModelSim-Altera software.

This design example implements a floating-point matrix inversion to calculate the inverse value of matrices in single-precision formats. The optional input ports (`enable` and `reset`) are enabled.

Table 2-2: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation waveform. The number of clock cycles obtained for each stage is based on the particular matrix size and parameter settings used in this design example.

Time	Event
0 ns – 10 ns	Start sequence: <ul style="list-style-type: none"> The <code>reset</code> signal deasserts. The <code>enable</code> signal asserts.
19.86 ns – 340 ns	Matrix input data load: <ul style="list-style-type: none"> The <code>load</code> signal asserts and remains high for 80 clock cycles. As long as the <code>load</code> signal is high, data for the input matrix is loaded row by row. Input data is burst in regularly, one at every clock cycle. The <code>load</code> signal deasserts at 340 ns. The deassertion of the <code>load</code> signal signifies the completion of the data load operation for the matrix.
27.5 ns	Processing stage: <ul style="list-style-type: none"> The <code>busy</code> signal asserts while the <code>done</code> signal deasserts. The assertion of the <code>busy</code> signal and the deassertion of the <code>done</code> signal indicate that the matrix inversion core is processing the input data. There are about 2500 clock cycles between the beginning of the processing stage and the first available output value.

Time	Event
12527.5 – 12922.5 ns	Output stage: <ul style="list-style-type: none"> • The <code>outvalid</code> signal asserts in intervals of 8 clock cycles. These series of assertions signify the availability of valid data for the output matrix on the <code>outdata[]</code> port. • The output is an 8 x 8 matrix. Data is burst out regularly, row by row. • At 12922.5 ns, the <code>busy</code> signal is asserted and the <code>done</code> signal is deasserted. • The assertion of the <code>busy</code> signal and the deassertion of the <code>done</code> signal indicate that the final output is written and a new matrix can be processed.

Sample Matrix Data

This section shows the random test data assigned to the input matrices and the results obtained from the matrix inversion operation.

The following two sets of results are computed:

- PC-based results—these are results obtained from running the simulation in Matlab.
- FPGA-based results—these are results obtained from running the simulation in ModelSim.

This table lists the input and output data values presented in IEEE-754 Floating-point format.

The difference between each result element of the PC-based and FPGA-based output matrices are as shown:

Result differences (in decimal)

253 529 304 259 431 431 439 523

529 534 315 537 455 452 450 531

304 315 359 309 256 257 524 311

259 537 309 264 220 441 448 532

431 455 256 220 361 364 376 449

431 452 257 441 364 366 375 447

439 450 524 448 376 375 377 447

523 531 311 532 449 447 447 527

The difference between the two output matrices are due to the following reasons:

- Method of processing—Matlab uses sequential processing while Modelsim uses parallel processing.
- Method of conversion—Matlab first computes in double-precision format, and then only converts the result into single-precision format. During this conversion, some units in the last place (ulp) are expected to be lost.

ALTERA_FP_MATRIX_INV Signals

Figure 2-5: ALTERA_FP_MATRIX_INV Signals

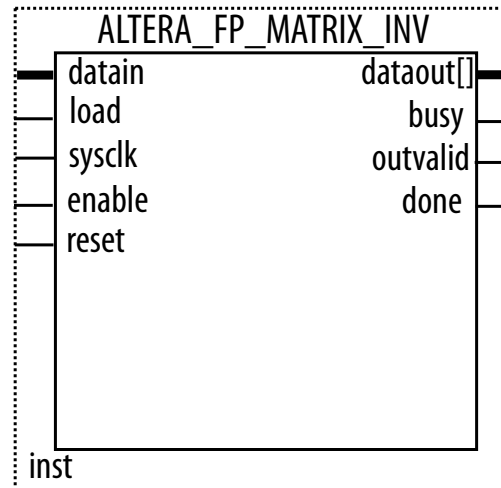

Table 2-4: ALTERA_FP_MATRIX_INV Input Signals

Port Name	Required	Description
sysclk	Yes	The clock input to the ALTERA_FP_MATRIX_INV IP core. This is the main system clock. All operations occur on the rising edge.
enable	No	Optional port. Allow calculation to take place when asserted. When deasserted, no operation will take place and the outputs are unchanged.
reset	No	Optional port. The core resets asynchronously when the <code>reset</code> signal is asserted.
load	Yes	When asserted, loads the <code>LOADDATA</code> bus into the memory.
loaddata	Yes	Single-precision 32-bit matrix input value. Matrices load row by row.

Table 2-5: ALTERA_FP_MATRIX_INV Output Signals

Port Name	Required	Description
ready	Yes	When asserted, the core preprocesses the input data. The calculate signal cannot be asserted until the <code>ready</code> signal is low.
outdata	Yes	Single-precision 32-bit matrix result value. The matrix result value is written out row by row.
outvalid	Yes	When asserted, a valid output data is available. An entire row of the result matrix is written out as a burst. There is a gap between row outputs, which will depend on the parameters.

Port Name	Required	Description
done	Yes	When asserted, the last output has been written. A new matrix multiply can be started with <code>calculate</code> . <code>done</code> will follow <code>ready</code> by some fixed amount, depending on the parameters.

ALTERA_FP_MATRIX_INV Parameters

Table 2-6: ALTERA_FP_MATRIX_INV Parameters

Port Name	Type	Required	Description
BLOCKS	Integer	No	The number of memory blocks for the double-buffered storage of matrix multiplication. The allowable range is from 2 to 16.
DIMENSION	Integer	Yes	<p>The number of rows in the matrix. As the matrix is square, this is also the number of columns in the matrix. The supported dimensions are 4 x 4, 6 x 6, 8 x 8, 16 x 16, 32 x 32, and 64 x 64. The maximum supported input dimension is 64 x 64.</p> <p>This parameter also acts as the <code>VECTORSIZE</code> when calling the <code>ALTERA_FP_MATRIX_MULT</code> IP core internally.</p>
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. The bias of the exponent is always set to $2(WIDTH_EXP-1) - 1$ (that is, 127 for single-precision format). <code>WIDTH_EXP</code> must be 8 for single-precision format and must be less than <code>WIDTH_MAN</code> . The available value for <code>WIDTH_EXP</code> is 8.
WIDTH_MAN	Integer	Yes	Specifies the precision of the mantissa. <code>WIDTH_MAN</code> must be 23 when <code>WIDTH_EXP</code> is 8. Otherwise, <code>WIDTH_MAN</code> must be a minimum of 31. <code>WIDTH_MAN</code> must be greater than <code>WIDTH_EXP</code> . The sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64. Current available value for <code>WIDTH_MAN</code> is only 23 for single precision.

ALTERA_FP_MATRIX_MULT Features

The ALTERA_FP_MATRIX_MULT IP core offers the following features:

- Multiplication of two matrices.
- Support for floating-point formats in single and double precisions.
- Support for configurable performance and resource usage.
- Avalon streaming interfaces and full QSys compliance.

ALTERA_FP_MATRIX_MULT Output Latency

The ALTERA_FP_MATRIX_MULT IP core does not have a fixed output latency. Instead, the IP core uses Avalon streaming interfaces and the `c_valid` signal on the output interface to indicate when output data is available.

ALTERA_FP_MATRIX_MULT Resource Utilization and Performance

These tables list the resource utilization and performance information for the ALTERA_FP_MATRIX_MULT IP core. The information was derived using the Quartus II software version 14.1.

ALTERA_FP_MATRIX_MULT Functional Description

The matrix multiplier in the ALTERA_FP_MATRIX_MULT IP core multiplies matrix A and matrix B to generate the output matrix C.

The following figure shows the equation:

Figure 3-1: ALTERA_FP_MATRIX_MULT Equation

$$C = A \cdot B$$

The matrix A and B can be loaded when the ready signal on their respective interfaces are asserted. When the input matrices are loaded, the core will start computing the output. Valid signal on the output interface will be asserted to indicate valid output data. The input data may be loaded at any time the ready signal is asserted even when the previously loaded data is still being computed.

Figure 3-2: Matrix Serialization Format

An input matrix with M rows and N columns must be input as shown in this figure, where the Row 0 and Column 0 element is first and Row M-1 and Column N-1 element is last. The result matrix will be output in the same format.

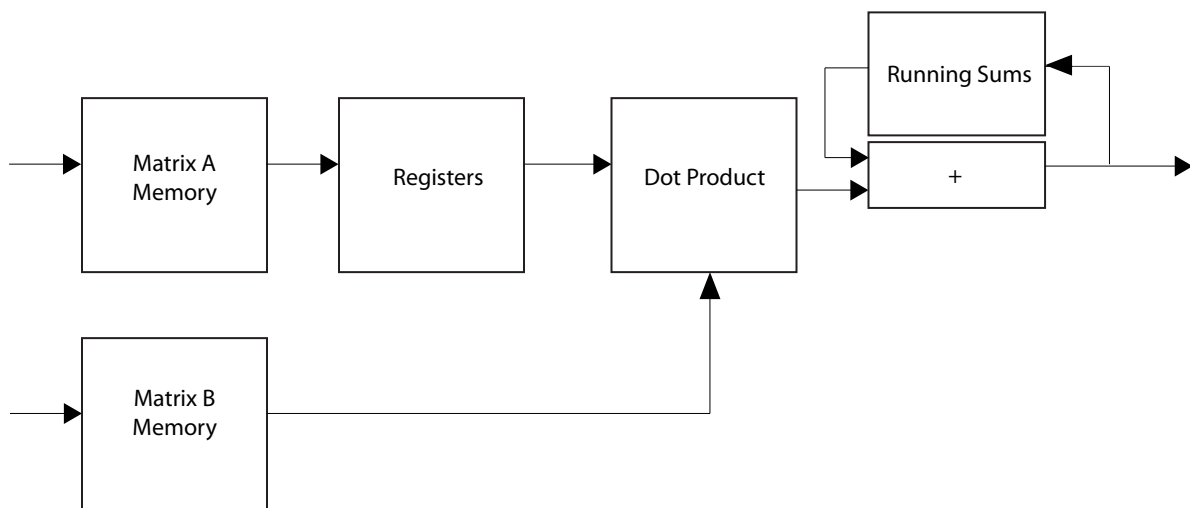

⁽¹⁾ Latency is the time take to compute a dot product and does not include the time taken to load the input matrices

The ALTERA_FP_MATRIX_MULT IP core consists of the following components:

- Memory blocks for the matrix A storage
- Memory blocks for the matrix B storage
- Dot product
- Accumulator

Figure 3-3: Top-Level View of the ALTERA_FP_MATRIX_MULT IP Core

This figure shows the top-level view of the ALTERA_FP_MATRIX_MULT IP core.

The following lists the key features of the architecture:

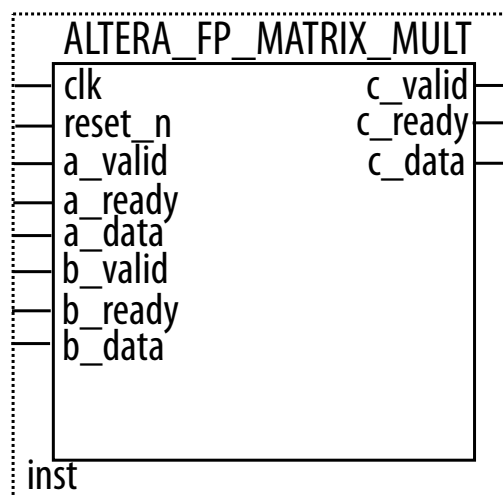

- Matrix A and B storage are double buffered to allow processing to happen in parallel with data loading.
- Where the number of columns of A (`A_COLUMNS`) and rows of B (same as `A_COLUMNS`) are greater than the size of the dot product (`VECTOR_SIZE`), the rows of A and columns of B are divided into sub rows and sub columns respectively, each containing `VECTOR_SIZE` elements. In this case, `A_COLUMNS/VECTOR_SIZE` iterations are needed to compute a full dot product corresponding to a single output element.
- Matrix B memory has sufficient bandwidth so that all the data needed for the dot product can be loaded at once.
- Matrix A memory is allocated with less bandwidth. The bandwidth of the matrix A is a parameter (`NUM_BLOCKS`) that you can control. A sub row of matrix A is loaded into local registers over a number of cycles before an iteration of the dot product. Once a sub row of Matrix A has been loaded into local registers, all partial dot products involving that sub row are computed before another sub row is loaded.
- For Arria 10 devices, where hardened single precision floating-point DSP blocks exist, those will be used for single precision floating point arithmetic.

The matrix multiply architecture is not optimized for sparse matrices and constant matrices.

ALTERA_FP_MATRIX_MULT Signals

Figure 3-4: ALTERA_FP_MATRIX_MULT Signals

This figure shows the signals for the ALTERA_FP_MATRIX_MULT IP core.

These tables list the signals for the ALTERA_FP_MATRIX_MULT IP core.

Table 3-2: ALTERA_FP_MATRIX_MULT Input Signals

Port Name	Required	Description
clk	Yes	The clock input port for the IP core.
reset_n	No	Asynchronous active low reset port.
a_data	Yes	Matrix A input data.
a_valid	Yes	Matrix A Avalon streaming valid signal. When this signal is asserted, data on a_data is valid.
b_data	Yes	Matrix B input data.
b_valid	Yes	Matrix B Avalon streaming valid signal. When this signal is asserted, data on b_data is valid.
c_ready	Yes	Matrix C Avalon streaming ready signal. Ready latency is 0.

Table 3-3: ALTERA_FP_MATRIX_MULT Output Signals

Port Name	Required	Description
a_ready	Yes	Matrix A Avalon streaming ready signal. Ready latency is 0.
b_ready	Yes	Matrix B Avalon streaming ready signal. Ready latency is 0.
c_data	Yes	Matrix C input data.
c_valid	Yes	Matrix C Avalon streaming valid signal. When this signal is asserted, data on c_data is valid.

ALTERA_FP_MATRIX_MULT Parameters

This table lists the parameters for the ALTERA_FP_MATRIX_MULT IP core.

Table 3-4: ALTERA_FP_MATRIX_MULT IP Core Parameters

Parameter	Value	Description
Format	Single (32 bit) or Double (64 bit)	The format of the input data.
Rows in Matrix A	2-256	Number of rows in matrix A.
Columns in Matrix A	8-256 Integer multiples of vector size. (Integer multiples of Memory Blocks.)	Number of columns in matrix A. This is also the number of rows in matrix B.
Rows in Matrix B	8-256	Number of rows in matrix B.
Columns of matrix B	2-256	Number of columns in matrix B.
Vector Size	Allowed values are 8,16, 32, 64, 96, and 128.	<p>The size of the dot product which can be computed in parallel. Where the number of columns of matrix A and rows of matrix B are greater than Vector Size a number of iterations are required to compute a full dot product.</p> <p>Vector Size also controls the matrix B memory configuration. Increasing the “Vector Size” increases the matrix B memory bandwidth and the number of memory blocks used.</p>
Memory Blocks	<p>The Vector Size must be an integer multiple of Memory Blocks. The number of memory blocks must be smaller than the vector size.</p> <p>The number of memory blocks must be greater than or equals to the ratio of vector size divided by the number of columns of matrix B.</p>	Controls the memory configuration of the matrix A storage. Increasing this number increases the memory bandwidth and the number of memory blocks used.

ALTERA_FP_ACC_CUSTOM Features

The ALTERA_FP_ACC_CUSTOM IP core offers the following features:

- Supports frequency driven cores.
- Supports VHDL RTL generation.
- Supports customization of the required range of the input and output values.

ALTERA_FP_ACC_CUSTOM Output Latency

The amount of latency is driven by the target frequency and the selected device family. You must set the desired frequency and the target device before generating the IP core. The IP core reports the latency when you set the parameters and when you generate the IP core. Then, use the reported latency to incorporate the IP core into your design.

ALTERA_FP_ACC_CUSTOM Signals

Figure 4-1: ALTERA_FP_ACC_CUSTOM

Table 4-2: ALTERA_FP_ACC_CUSTOM Input Ports

Port Name	Required	Description
clk	Yes	All input signals, otherwise explicitly stated, must be synchronous to this clock
areset	Yes	Asynchronous active-high reset. Deassert this signal synchronously to the input clock to avoid metastability issues.
en	No	Global enable signal. This port is optional.
x	Yes	Data input port.
n	Yes	Boolean port which signals the beginning of a new data set to be accumulated. This should go high together with the first element in the new data set and should go low the next cycle. The data sets may be of variable length and a new data set may be started at any time. The accumulation result for an input will be available after the reported latency.

Table 4-3: ALTERA_FP_ACC_CUSTOM Output Ports

Port Name	Required	Description
r	Yes	The running value of the accumulation.

Port Name	Required	Description
xo	Yes	The overflow flag for port x. The signal goes high when the exponent of the input x is larger than maxMSBX. The signal remains high for the entire data set. This flag invalidates port r. You should consider increasing maxMSBX. This flag also indicate infinity and NaN.
xu	Yes	The underflow flag for port x. The signal goes high when the exponent of the input x is smaller than LSBA. The signal remains high for the entire data set. This flag does not invalidate port r. You should consider lowering LSBA.
ao	Yes	The overflow flag for Accumulator. The signal goes high when the exponent of the accumulated value is larger than MSBA. The signal remains high for the entire data set. This flag invalidates port r. You should consider increasing MSBA.

ALTERA_FP_ACC_CUSTOM Parameters

Table 4-4: ALTERA_FP_ACC_CUSTOM Parameters

Category	Parameter	Values	Description
Input Data	Floating point format	single , double	Choose the floating point format of the input data values. The output data values of the accumulator is in the same format. The default is single .
	maxMSBX	—	The maximum weight of the MSB of an input. For example, when adding probabilities in the 0 to 1 range set this weight to $\text{ceil}(\log_2(1))=0$. The xo output signal goes high when the MSB of an input value has a weight larger than maxMSBX. The result of the accumulation is then invalid. If you are unsure about the range of the inputs, then set the maxMSBX parameter to MSBA, at the possible expense of increased resource usage. The default value is 12 .

Category	Parameter	Values	Description
Accumulator Size	MSBA	—	<p>The weight of the MSB of the accumulator. For example, in a financial simulation, if the value of a stock cannot exceed 100,000 dollars, use a value of $\text{ceil}(\log_2(100000))=17$.</p> <p>In a circuit simulation where the circuit adds numbers in the 0 to 1 range, for one year, at 400 MHz, use a value of $\text{ceil}(\log_2(365 \times 60 \times 60 \times 24 \times 400 \times 10^6))=54$.</p> <p>The <code>ao</code> output signal goes high when the MSB of the accumulated value has a weight larger than MSBA. The result of the accumulation is then invalid. Altera recommends adding a few guard bits to avoid possible accumulator overflow. A few guard bits have little impact on the accumulator size.</p> <p>The default value is 20.</p>
	LSBA	—	<p>The weight of the LSB of the accumulator and the accuracy of the accumulator. Because an N term accumulation can invalidate the $\log_2(N)$ LSBs of the accumulator, you must consider the length of the accumulation and the range of the inputs when setting this parameter.</p> <p>For example, if a 2^{-30} accuracy is required over an accumulation of 1024 numbers, then set the LSBA to:</p> $(-30 - \log_2(1024)) = -40.$ <p>Any input $2^e \times 1.F$, where F is the mantissa and e is less than the LSBA will be shifted out of the accumulator. The <code>au</code> output signal goes high to indicate this situation.</p> <p>The default value is -26.</p>
Required Performance	Target frequency	Any positive integer value.	<p>Choose the frequency in MHz at which this core is expected to run. This together with the target device family will determine the amount of pipelining in the core.</p> <p>The default value is 200 MHz.</p>
Optional	Generate an enable port	—	<p>Choose if the accumulator should have an enable signal.</p> <p>This parameter is disabled by default.</p>

Category	Parameter	Values	Description
Report	—	—	Reports the latency of the device, which is the number of cycles it takes for an accumulation to propagate through the block from input to output.

ALTFP_ADD_SUB Features

The ALTFP_ADD_SUB IP core offers the following features:

- Dynamically configurable adder and subtracter functions.
- Optional exception handling output ports such as zero, overflow, underflow, and nan.
- Optimization of speed and area.

ALTFP_ADD_SUB Output Latency

The output latency options for the ALTFP_ADD_SUB IP core are the same for all three precision formats—single, double, and single-extended. The options available are 7, 8, 9, 10, 11, 12, 13, and 14 clock cycles.

ALTFP_ADD_SUM Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

Figure 5-1: ALTFP_ADD_SUB Simulation Waveform

This design example implements a floating-point adder for the addition of double-precision format numbers. All the optional input ports (`clk_en` and `aclr`) and optional output ports (`overflow`, `underflow`, `zero`, and `nan`) are enabled.

In this example, the output latency of the multiplier is set to 7 clock cycles. Every addition result appears at the `result[]` port 7 clock cycles after the input values are captured on the `dataa[]` and `datab[]` ports.

The following lists the inputs and corresponding outputs obtained from the simulation waveform.

Table 5-3: Summary of Input Values and Corresponding Outputs

Time	Event
0 ns, start-up	<p><code>dataa[]</code> value: 0000 0000 0000 0000h</p> <p><code>datab[]</code> value: 7FF0 0000 0000 0000h</p> <p>Output value: All values seen on the output port before the 7th clock cycle are merely due to the behavior of the system during startup and should be disregarded.</p>
4250 ns	<p>Output value: 7FF0 0000 0000 0000h</p> <p>Exception handling ports: <code>overflow</code> asserts</p> <p>The addition of zero at the input port <code>dataa[]</code>, and infinity value at the input port <code>datab[]</code> results in infinity value.</p>
40,511 ns	<p><code>dataa[]</code> value: 0000 0000 0000 0000h</p> <p><code>datab[]</code> value: 0000 0000 1000 0123h</p> <p>This is the addition of a zero and a denormal value.</p>
43,750 ns	<p>Output value: 0000 0000 0000 0000h</p> <p>Exception handling ports: <code>zero</code> remains asserted.</p> <p>Denormal inputs are not supported and are forced to zero before addition takes place. This results in a zero.</p>

ALTFP_ADD_SUB Signals

Figure 5-2: ALTFP_ADD_SUB

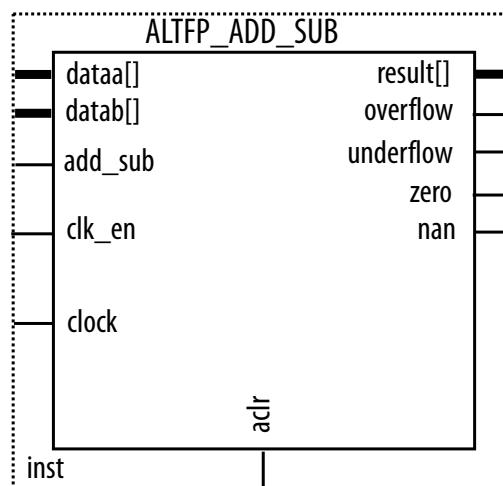

Table 5-4: ALTFP_ADD_SUB Input Ports

Port Name	Required	Description
aclr	No	Asynchronous clear input for floating-point adder or subtractor. The source is asynchronously reset when the <code>aclr</code> signal is asserted high.
add_sub	No	Optional input port to enable dynamic switching between the adder and subtractor functions. The <code>add_sub</code> port must be used when the <code>DIRECTION</code> parameter is set to <code>VARIABLE</code> . When the <code>add_sub</code> port is high, <code>result[] = dataa[] + datab[]</code> , otherwise, <code>result[] = dataa[] - datab[]</code> .
clk_en	No	Clock enable to the floating-point adder or subtractor. This port allows addition or subtraction to occur when asserted high. When asserted low, no operations occur and the outputs are unchanged.
clock	Yes	Clock input to the IP core.
dataa[]	Yes	Data input to the floating-point adder or subtractor. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa bits. The size of this port is the total width of the sign bit, the exponent bits, and the mantissa bits.
datab[]	Yes	Data input to the floating-point adder or subtractor. This port is configured in the same way as <code>dataa[]</code> .

Table 5-5: ALTFP_ADD_SUB Output Ports

Port Name	Required	Description
nan	Yes	NaN exception output. Asserted when an illegal addition or subtraction occurs, such as infinity minus infinity. When an invalid addition or subtraction occurs, a NaN value is output to the <code>result[]</code> port. Any adding or subtracting involving NaN values also produces a NaN value.

Port Name	Required	Description
overflow	Yes	Overflow exception port. Asserted when the result of the addition or subtraction, after rounding, exceeds or reaches infinity. Infinity is defined as a number in which the exponent exceeds $2^{\text{WIDTH_EXP}} - 1$.
result[]	Yes	Floating-point output result. Like the input values, the MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.
underflow	Yes	Underflow port for the adder or subtractor. Asserted when the result of the addition or subtraction, after rounding, the value is zero and the inputs are not equal. The underflow port is also asserted when the result is a denormalized number.
zero	No	Zero port for the adder or subtractor. Asserted when the result[] port is zero.

ALTFP_ADD_SUB Parameters

Table 5-6: ALTFP_ADD_SUB Parameters

Parameter Name	Type	Required	Description
DIRECTION	String	Yes	Specifies addition or subtraction operations. Values are ADD, SUB, or VARIABLE. If this parameter is not specified, the default is ADD. When the value is VARIABLE, the add_sub port determines whether the operation is addition or subtraction. The add_sub port must be connected if the DIRECTION parameter is set to VARIABLE. If the value is ADD or SUB, the add_sub port is ignored.
PIPELINE	Integer	No	Specifies the latency in clock cycles used in the ALTFP_ADD_SUB IP core. The PIPELINE parameter supports values of 7 through 14. If this parameter is not specified, the default value is 11. In general, a higher pipeline value produces better f_{MAX} performance.
ROUNDING	String	Yes	Specifies the rounding mode. The default value is TO_NEAREST. Other rounding modes are currently not supported.
OPTIMIZE	String	No	Defines the design preference, whether the design is optimized for speed (faster f_{MAX}), or optimized for area (lower resource count). Values are SPEED and AREA. If this parameter is not specified, the default is SPEED.

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	No	Specifies the precision of the exponent. The bias of the exponent is always set to 2 (WIDTH_EXP-1) -1 (that is, 127 for single-precision format and 1023 for double-precision format). The WIDTH_EXP parameter must be 8 for the single-precision mode and 11 for the double-precision mode, or a minimum of 11 for the single-extended precision mode. The WIDTH_EXP parameter must be less than the WIDTH_MAN parameter. The sum of WIDTH_EXP and the WIDTH_MAN parameters must be less than 64. If this parameter is not specified, the default is 8.
WIDTH_MAN	Integer	No	Specifies the precision of the mantissa. The WIDTH_MAN parameter must be 23 (to comply with the IEEE-754 standard for the single-precision mode) when the WIDTH_EXP parameter is 8. Otherwise, the WIDTH_MAN parameter must have a value that is greater than or equal to 31. The WIDTH_MAN parameter must be greater than the WIDTH_EXP parameter. The sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64. If this parameter is not specified, the default is 23.

ALTFP_DIV Features

The ALTFP_DIV IP core offers the following features:

- Division functions.
- Optional exception handling output ports such as zero, division_by_zero, overflow, underflow, and nan.
- Optimization of speed and area.
- Low latency option.

ALTFP_DIV Output Latency

The output latency options for the ALTFP_DIV IP core differs depending on the precision selected, the width of the mantissa, or both. You have the choice of selecting the smaller figures of clock cycles delay in your design if the low latency option is desired.

Table 6-1: Latency Options for Each Operation

Precision	Mantissa Width	Latency (in clock cycles)
Single	23	6, 14, 33
Double	52	10, 24, 61

ALTFP_DIV Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

Figure 6-1: ALTFP DIV Simulation Waveform

This figure shows the expected simulation results in the ModelSim-Altera software.

This design example implements a floating-point divider for the division of single-precision numbers with a low latency option. The output latency is 6, hence every division generates the output result 6 clock cycles later.

Table 6-4: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation in the waveform.

Time	Event
0 ns, start-up	<p>dataa[] value: 0000 0000h</p> <p>datab[] value: 0000 0000h</p> <p>Output value: The undefined value is seen on the <code>result[]</code> port, which is ignored. All values seen on the output port before the 6th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.</p>
17600 ns	<p>Output value: 7FC0 0000h</p> <p>Exception handling ports: <code>nan asserts</code></p> <p>The division of zeros result in a NaN.</p>
2000 ns	<p>dataa[] value: 2D0B 496Ah</p> <p>datab[] value: 3A5A FC26h</p> <p>Both inputs hold normal values.</p>
20800 ns	<p>Output result: 321F 6EC6h</p> <p>Exception output ports: <code>nan deasserts</code></p> <p>The division of two normal value results in a normal value.</p>
11000 ns	<p>dataa[] value: 046E 78BCh</p> <p>datab[] value: 6798 698Bh</p> <p>Both inputs hold normal values.</p>
27200 ns	<p>Output value: 0h</p> <p>Exception handling ports: <code>underflow</code> and <code>zero asserts</code></p> <p>The division of the two normal values results in a denormal value. As denormal values are not supported, the result is zero and the <code>underflow</code> port asserts. The <code>zero</code> port is also asserted to indicate that the result is zero.</p>
2600 ns	<p>dataa[] value: 0D72 54A8h</p> <p>datab[] value: 0070 0000h</p> <p>The input port <code>dataa[]</code> holds a normal value while the input port <code>datab[]</code> holds a denormal value.</p>
36800 ns	<p>Output value: 7F80 0000h</p> <p>Exception handling ports: <code>division_by_zero asserts</code></p> <p>Denormal numbers are forced-zero values, therefore, attempts to divide a normal value with a zero result in an infinity value.</p>

ALTFP_DIV Signals

Figure 6-2: ALTFP_DIV Signals

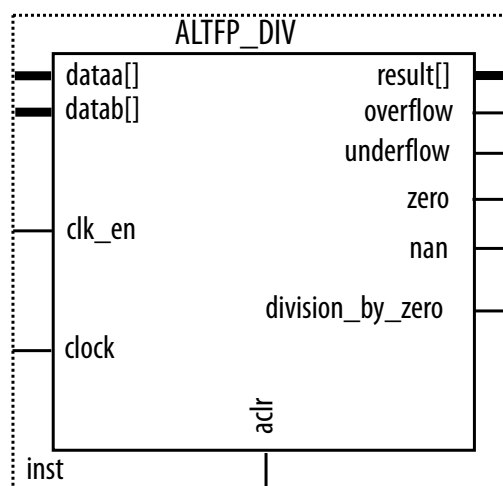

Table 6-5: ALTFP_DIV Input Signals

Port Name	Required	Description
aclr	No	Asynchronous clear input for the floating-point divider. The source is asynchronously reset when the <code>aclr</code> signal is asserted high.
clock	Yes	Clock input to the IP core.
clk_en	No	Clock enable to the floating-point divider. This port enables division. This signal is active high. When this signal is low, no division takes place and the outputs remain the same.
dataa[]	Yes	Numerator data input. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits and mantissa bits.
datab[]	Yes	Denominator data input. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits and mantissa bits.

Table 6-6: ALTFP_DIV Output Signals

Port Name	Required	Description
result[]	Yes	Divider output port. The division result (after rounding). As with the input values, the MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.

Port Name	Required	Description
overflow	No	Overflow port for the divider. Asserted when the result of the division (after rounding) exceeds or reaches infinity. Infinity is defined as a number in which the exponent exceeds $2^{WIDTH_EXP}-1$.
underflow	No	Underflow port for the divider. Asserted when the result of the division (after rounding) is zero even though neither of the inputs to the divider is zero, or when the result is a denormalized number.
zero	No	Zero port for the divider. Asserted when the value of <code>result[]</code> is zero.
division_by_zero	No	Division-by-zero output port for the divider. Asserted when the value of <code>datab[]</code> is a zero.
nan	No	NaN port. Asserted when an invalid division occurs, such as infinity dividing infinity or zero dividing zero. A NaN value appears as output at the <code>result[]</code> port. Any division of a NaN value causes the <code>nan</code> output port to be asserted.

ALTFP_DIV Parameters

Table 6-7: ALTFP_DIV Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	<p>Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $(2^{(WIDTH_EXP - 1)}) - 1$, that is, 127 for single precision and 1023 for double precision. The value of <code>WIDTH_EXP</code> must be 8 for single precision, 11 for double precision, and a minimum of 11 for single extended precision.</p> <p>The value of <code>WIDTH_EXP</code> must be less than the value of <code>WIDTH_MAN</code>, and the sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64.</p>
WIDTH_MAN	Integer	Yes	<p>Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. When <code>WIDTH_EXP</code> is 8 and the floating-point format is the single-precision format, the <code>WIDTH_MAN</code> value must be 23. Otherwise, the value of <code>WIDTH_MAN</code> must be a minimum of 31.</p> <p>The value of <code>WIDTH_MAN</code> must be greater than the value of <code>WIDTH_EXP</code>, and the sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64.</p>
ROUNDING	String	Yes	Specifies the rounding mode. The default value is <code>TO_NEAREST</code> . The floating-point divider does not support other rounding modes.

Parameter Name	Type	Required	Description
OPTIMIZE	String	No	Specifies whether to optimize for area or for speed. Values are <code>AREA</code> and <code>SPEED</code> . A value of <code>AREA</code> optimizes the design using less total logic utilization or resources. A value of <code>SPEED</code> optimizes the design for better performance. If this parameter is not specified, the default value is <code>SPEED</code> .
PIPELINE	Integer	No	<p>Specifies the number of clock cycles needed to produce the result. For the single-precision format, the latency options are 33, 14 or 6. For the double-precision format, the latency options are 61, 24 or 10.</p> <p>For the single-extended precision format, the value ranges from a minimum of 41 to a maximum of 61. For the low-latency option, the latency is determined from the mantissa width. For a mantissa width of 31 to 40 bits, the value is 8 or 18. For a mantissa width of 41 bits or more, the value is 10 or 24.</p>

ALTFP_MULT IP Core Features

The ALTFP_MULT IP core offers the following features:

- Multiplication functions.
- Optional exception handling output ports such as zero, overflow, underflow, and nan.
- Optional dedicated multiplier circuitries in Cyclone and Stratix series.

ALTFP_MULT Output Latency

The output latency options for the ALTFP_MULT IP core are similar for all precisions.

Table 7-1: Latency Options for Each Precision Format

Precision	Mantissa Width	Latency (in clock cycles)
Single	23	5, 6, 10,11
Double	52	5, 6, 10,11
Single-Extended	31–52	5, 6, 10,11

ALTFP_MULT Design Example: Understanding the Simulation Waveform

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

Figure 7-1: ALTFP_MULT Simulation Waveform

This figure shows the expected simulation results in the ModelSim-Altera software.

This design example implements a floating-point multiplier for the multiplication of double-precision format numbers. All the optional input ports (`clk_en` and `aclr`) and output ports (`overflow`, `underflow`, `zero`, and `nan`) are enabled.

In this example, the latency is set to 6 clock cycles. Therefore, every multiplication result appears at the result port 6 clock cycles later.

Table 7-4: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation in the waveform.

Time	Event
0 ns, start-up	<p><code>dataa[]</code> value: 0000 0000 0000 0000h</p> <p><code>datab[]</code> value: 4037 742C 3C9E ECC0h</p> <p>Output value: All values seen on the output port before the 6th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.</p>
110 ns	<p>Output value: 0000 0000 0000 0000h</p> <p>Exception handling ports: <code>zero</code> asserts</p> <p>The multiplication of zero at the input port <code>dataa[]</code>, and a non-zero value at the input port <code>datab[]</code> results in a zero.</p>
600 ns	<p><code>dataa[]</code> value: 7FF0 0000 0000 0000h</p> <p><code>datab[]</code> value: 4037 742C 3C9E ECC0h</p> <p>This is the multiplication of an infinity value and a normal value.</p>
710 ns	<p>Output value: 7FF0 0000 0000 0000h</p> <p>Exception handling ports: <code>overflow</code> asserts</p> <p>The multiplication of an infinity value and a normal value results in infinity. All multiplications with an infinity value results in infinity except when infinity is multiplied with a zero.</p>

Parameters

Table 7-5: ALTFP_MULT Megafunction Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	No	Specifies the value of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always $2^{(WIDTH_EXP - 1)} - 1$ (that is, 127 for the single-precision format and 1023 for the double-precision format). WIDTH_EXP must be 8 for the single-precision format or a minimum of 11 for the double-precision format and the single-extended precision format. WIDTH_EXP must be less than WIDTH_MAN. The sum of WIDTH_EXP and WIDTH_MAN must be less than 64.
WIDTH_MAN	Integer	No	Specifies the value of the mantissa. If this parameter is not specified, the default is 23. When WIDTH_EXP is 8 and the floating-point format is single-precision, the WIDTH_MAN value must be 23; otherwise, the value of WIDTH_MAN must be a minimum of 31. The WIDTH_MAN value must always be greater than the WIDTH_EXP value. The sum of WIDTH_EXP and WIDTH_MAN must be less than 64.
DEDICATED_MULTIPLIER_CIRCUITRY	String	No	Specifies whether to use dedicated multiplier circuitry. Values are AUTO, YES, or NO. If this parameter is not specified, the default is AUTO. If a device does not have dedicated multiplier circuitry, the DEDICATED_MULTIPLIER_CIRCUITRY parameter has no effect and defaults to NO.
PIPELINE	Integer	No	Specifies the number of clock cycles needed to produce the multiplied result. Values are 5, 6, 10, and 11. If this parameter is not specified, the default is 5.

ALTFP_MULT Signals

Table 7-6: ALTFP_MULT IP Core Input Signals

Port Name	Required	Description
clock	Yes	Clock input to the IP core.
clk_en	No	Clock enable. Allows multiplication to take place when asserted high. When signal is asserted low, no multiplication occurs and the outputs remain unchanged.

Port Name	Required	Description
aclr	No	Synchronous clear. Source is asynchronously reset when asserted high.
dataa[]	Yes	Floating-point input data input to the multiplier. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.
datab[]	Yes	Floating-point input data to the multiplier. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.

Table 7-7: ALTFP_MULT IP Core Output Signals

Port Name	Required	Description
result[]	Yes	Output port for the multiplier. The floating-point result after rounding. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa.
overflow	No	Overflow port for the multiplier. Asserted when the result of the multiplication, after rounding, exceeds or reaches infinity. Infinity is defined as a number in which the exponent exceeds $2^{\text{WIDTH_EXP}-1}$.
underflow	No	Underflow port for the multiplier. Asserted when the result of the multiplication (after rounding) is 0 while none of the inputs to the multiplication is 0, or asserted when the result is a denormalized number.
zero	No	Zero port for the multiplier. Asserted when the value of <code>result[]</code> is 0.
nan	No	NaN port for the multiplier. This port is asserted when an invalid multiplication occurs, such as the multiplication of infinity and zero. In this case, a NaN value is the output generated at the <code>result[]</code> port. The multiplication of any value and NaN produces NaN.

Figure 8-2: ALTFP_SQRT ModelSim Simulation Waveform (Output Data)

This design example implements a floating-point square root function for single-precision format numbers with all the exception output ports instantiated. The output ports include overflow, zero, and nan.

The output latency is 28 clock cycles. Every square root computation generates the output result 28 clock cycles later.

Table 8-3: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation in the waveforms.

Time	Event
0 ns, start-up	Output value: All values seen on the output port before the 28th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.
2 000 ns	data[] value: 2D0B 496Ah The data input is a normal number.
84 000 ns	Output value: 363C D4EBh The square root computation of a normal input results in a normal output.
14 000 ns	data[] value: 0000 0000h
96 000 ns	Output value: 0000 0000h Exception handling ports: zero asserts The square root computation of zero results in a zero.
23 000 ns	data[] value: 7F80 0000h The input is infinity.
105 000 ns	Output value: 7F80 0000h Exception handling ports: overflow asserts

ALTFP_SQRT Signals

Figure 8-3: ALTFP_SQRT Signals

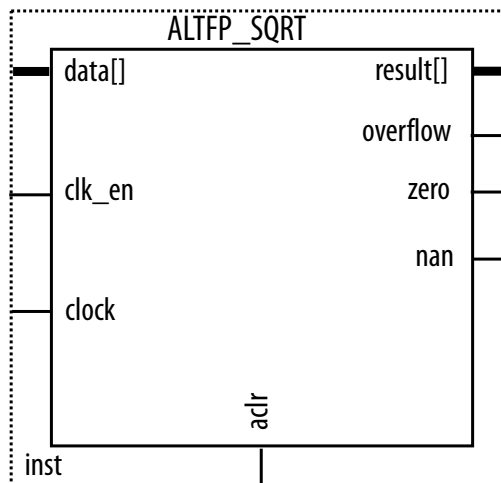

Table 8-4: ALTFP_SQRT IP Core Input Signals

Port Name	Required	Description
clock	Yes	Clock input to the IP core.
clk_en	No	Clock enable that allows square root operations when the port is asserted high. When the port is asserted low, no operation occurs and the outputs remain unchanged.
aclr	No	Asynchronous clear. When the <code>aclr</code> port is asserted high, the function is asynchronously reset.
	Yes	Floating-point input data. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.

Table 8-5: ALTFP_SQRT IP Core Output Signals

Port Name	Required	Description
result[]	Yes	Square root output port for the floating-point result. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.
overflow	Yes	Overflow port. Asserted when the result of the square root (after rounding) exceeds or reaches infinity. Infinity is defined as a number in which the exponent exceeds $2^{\text{WIDTH_EXP}} - 1$.
zero	Yes	Zero port. Asserted when the value of the <code>result[]</code> port is 0.
nan	Yes	NaN port. Asserted when an invalid square root occurs, such as negative numbers or NaN inputs.

ALTFP_SQRT Parameters

Table 8-6: ALTFP_SQRT Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2^{(WIDTH_EXP - 1)} - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of the WIDTH_EXP parameter must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of the WIDTH_EXP parameter must be less than the value of the WIDTH_MAN parameter, and the sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
WIDTH_MAN	Integer	Yes	Specifies the value of the mantissa. If this parameter is not specified, the default is 23. When the WIDTH_EXP parameter is 8 and the floating-point format is single-precision, the WIDTH_MAN parameter value must be 23. Otherwise, the value of the WIDTH_MAN parameter must be a minimum of 31. The value of the WIDTH_MAN parameter must be greater than the value of the WIDTH_EXP parameter. The sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
ROUNDING	String	Yes	Specifies the rounding mode. The default value is TO_NEAREST. Other rounding modes are not supported.
PIPELINE	Integer	Yes	Specifies the number of clock cycles for the square root results of the <code>result[]</code> port. Values are WIDTH_MAN + 5 and $((WIDTH_MAN + 5/2) + 2)$ as specified by truncating the radix point.

You can use the ports and parameters available to customize the ALTFP_EXP IP core according to your application.

ALTFP_EXP Features

The ALTFP_EXP IP core offers the following features:

- Exponential value of a given input.
- Optional exception handling output ports such as zero, overflow, underflow, and nan.

Output Latency

The output latency options for the ALTFP_EXP megafunction differs depending on the precision selected, the width of the mantissa, or both.

Precision	Mantissa Width	Latency (in clock cycles)
Single	23	17
Double	52	25
Single-extended	31 – 38	22
	39 – 52	25

ALTFP_EXP Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

These figures show the expected simulation results in the ModelSim-Altera software.

Figure 9-1: ALTFP_EXP ModelSim Simulation Waveform (Input Data)

Figure 9-2: ALTFP_EXP ModelSim Simulation Waveform (Output Data)

This design example implements a floating-point exponential for the single-precision format numbers. The optional input ports (clk_en and aclr) and all four exception handling output ports (nan, overflow, underflow, and zero) are enabled.

For single-precision format numbers, the latency is fixed at 17 clock cycles. Therefore, every exponential operation outputs the results 17 clock cycles later.

Table 9-3: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation in the waveforms.

Time	Event
0 ns, start-up	data[] value: 1A03 568Ch Output value: An undefined value is seen on the result[] port, which is ignored. All values seen on the output port before the 17th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.

Time	Event
82.5 ns	<p>Output value: 3F80 0000h</p> <p>As the input value of 1A03568Ch is a very small number, it is seen as a value that is approaching zero, and the result approaches 1 (which is represented by 3F800000). Exponential operations carried out on numbers of very small magnitudes result in a 1 and assert the <code>underflow</code> flag.</p> <p>Exception handling ports: <code>underflow</code> asserts</p>
30 ns	<p><code>data[]</code> value: F3FC DEFFh</p> <p>This is a normal negative value of a very large magnitude.</p>
112.5 ns	<p>Output value: 0000 0000h</p> <p>The outcome of exponential operations on negative numbers of very large magnitudes approaches zero.</p> <p>Exception handling ports: <code>underflow</code> remains asserted</p>
60 ns	<p><code>data[]</code> value: 7F80 0000h</p> <p>This is a positive infinite value.</p>
142.5 ns	<p>Output value: 7F80 0000h</p> <p>The operation on positive infinite values results in infinity.</p> <p>Exception handling ports: <code>underflow</code> deasserts, <code>overflow</code> asserts</p>
90 ns	<p><code>data[]</code> value: 7FC0 0000h</p> <p>This is a NaN.</p>
172.5 ns	<p>Output value: 7FC0 0000h</p> <p>The exponential of a NaN results in a NaN.</p> <p>Exception handling ports: <code>nan</code> asserts</p>
120 ns	<p><code>data[]</code> value: C1D4 49BAh</p> <p>This is a normal value.</p>
202.5 ns	<p>Output value: 2C52 5981h</p> <p>The result is a normal value.</p> <p>Exception handling ports: <code>nan</code> deasserts</p>

ALTFP_EXP Signals

Figure 9-3: ALTFP_EXP Signals

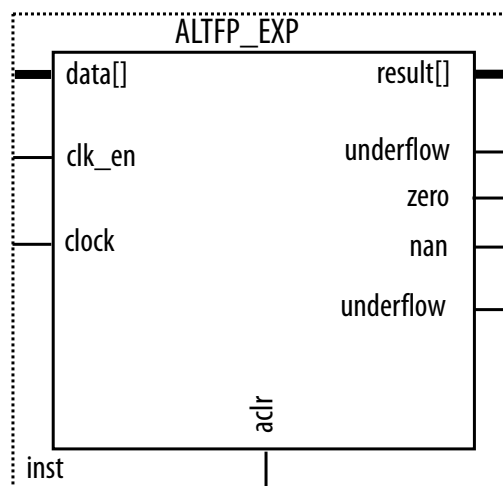

Table 9-4: ALTFP_EXP IP Core Input Signals

Port Name	Required	Description
<code>aclr</code>	No	Asynchronous clear. When the <code>aclr</code> port is asserted high the function is asynchronously reset.
<code>clk_en</code>	No	Clock enable. When the <code>clk_en</code> port is asserted high, an exponential value operation takes place. When this signal is asserted low, no operation occurs and the outputs remain unchanged.
<code>clock</code>	Yes	Clock input to the IP core.
<code>data[]</code>	Yes	Floating-point input data. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of the sign bit, exponent bits, and mantissa bits.

Table 9-5: ALTFP_EXP IP Core Output Signals

Port Name	Required	Description
<code>result[]</code>	Yes	The floating-point exponential result of the value at <code>data[]</code> . The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.
<code>overflow</code>	No	Overflow exception output. Asserted when the result of the operation (after rounding) is infinite.
<code>underflow</code>	No	Underflow exception output. Asserted when the result of the exponential approaches 1 (from numbers of very small magnitude), or when the result approaches 0 (from negative numbers of very large magnitudes).
<code>zero</code>	No	Zero exception output. Asserted when the value in the <code>result[]</code> port is zero.

Port Name	Required	Description
nan	No	NaN exception output. Asserted when an invalid operation occurs. Any operation involving NaN also asserts the nan port.

ALTFP_EXP Parameters

Table 9-6: ALTFP_EXP IP Core Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2^{(WIDTH_EXP - 1)} - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of the WIDTH_EXP parameter must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of the WIDTH_EXP parameter must be less than the value of the WIDTH_MAN parameter, and the sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
WIDTH_MAN	Integer	Yes	Specifies the value of the mantissa. If this parameter is not specified, the default is 23. When the WIDTH_EXP parameter is 8 and the floating-point format is single-precision, the WIDTH_MAN parameter value must be 23. Otherwise, the value of the WIDTH_MAN parameter must be a minimum of 31. The value of the WIDTH_MAN parameter must be greater than the value of the WIDTH_EXP parameter. The sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
PIPELINE	Integer	Yes	Specifies the amount of latency, expressed in clock cycles, used in the ALTFP_EXP IP core. Acceptable pipeline values are 17, 22, and 25 cycles of latency. Create the ALTFP_EXP IP core with the MegaWizard Plug-In Manager to calculate the value for this parameter.
ROUNDING	String	Yes	Specifies the rounding mode. The default value is TO_NEAREST. Other rounding modes are not supported.

ALTFP_INV Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

- ⁽³⁾ Any calculated or computed **denormal** output is replaced by a zero and asserts the zero and underflow flags.
- ⁽⁴⁾ Any denormal input is treated as a zero before going through the inverse process.

These figures show the expected simulation results in the ModelSim-Altera software.

Figure 10-1: ALTFP_INV ModelSim Simulation Waveform (Input Data)

Figure 10-2: ALTFP_INV ModelSim Simulation Waveform (Output Data)

This design example implements a floating-point inverse for single-precision format numbers. The optional input ports (`clk_en` and `aclr`) and all four exception handling output ports (`division_by_zero`, `nan`, `zero`, and `underflow`) are enabled.

The latency is fixed at 20 clock cycles; therefore, every inverse operation outputs results 20 clock cycles later.

This table lists the inputs and corresponding outputs obtained from the simulation in the waveforms.

Table 10-3: Summary of Input Values and Corresponding Outputs

Time	Event
0 ns, start-up	<p><code>data[]</code> value: 34A2 E42Fh</p> <p>Output value: An undefined value is seen on the <code>result[]</code> port, which is ignored. All values seen on the output port before the 20th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.</p>
97.5 ns	<p>Output value: 4A49 2A2Fh</p> <p>Exception handling ports: <code>division_by_zero</code> deasserts</p> <p>The inverse of a normal number results in a normal value.</p>
10 ns	<p><code>data[]</code> value: 7F80 0000h</p> <p>This is an infinity value.</p>

Time	Event
107.5 ns	Output value: 0000 0000h Exception handling ports: <code>zero</code> asserts The inverse of an infinity value produces a zero.
60 ns	<code>data[]</code> value: 7FC0 0000h This is a NaN.
157.5 ns	Output value: 7FC0 0000h Exception handling ports: <code>nan</code> asserts The inverse of a NaN results in a NaN
70 ns	<code>data[]</code> value: 0000 1000h This is a denormal number.
167.5 ns	Output value: 7F80 0000h Exception handling ports: <code>nan deasserts</code> , <code>division_by_zero</code> asserts Denormal numbers are forced-zero values, therefore, the inverse of a zero results in infinity.

Ports

Table 10-4: ALTFP_INV Megafunction Input Ports

Port Name	Required	Description
<code>aclr</code>	No	Asynchronous clear. When the <code>aclr</code> port is asserted high, the function is asynchronously cleared.
<code>clk_en</code>	No	Clock enable. When the <code>clk_en</code> port is asserted high, an inversion value operation takes place. When signal is asserted low, no operation occurs and the outputs remain unchanged.
<code>clock</code>	Yes	Clock input to the megafunction.
<code>data[]</code>	Yes	Floating-point input data. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of the sign bit, exponent bits, and mantissa bits.

Table 10-5: ALTFP_INV Megafunction Output Ports

Port Name	Required	Description
result[]	Yes	The floating-point inverse result of the value at the <code>data[]</code> input port. The MSB is the sign, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.
underflow	No	Underflow exception output. Asserted when the result of the inversion (after rounding) is a denormalized number.
zero	No	Zero exception output. Asserted when the value at the <code>result[]</code> port is a zero.
division_by_zero	No	Division-by-zero exception output. Asserted when the denominator input is a zero.
nan	No	NaN exception output. Asserted when an invalid inversion occurs, such as the inversion of NaN. In this case, a NaN value is output to the <code>result[]</code> port. Any operation involving NaN also asserts the <code>nan</code> port.

Parameters

Table 10-6: ALTFP_INV Megafunction Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2^{(WIDTH_EXP - 1)} - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of the <code>WIDTH_EXP</code> parameter must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of the <code>WIDTH_EXP</code> parameter must be less than the value of the <code>WIDTH_MAN</code> parameter, and the sum of the <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> parameters must be less than 64.

Parameter Name	Type	Required	Description
WIDTH_MAN	Integer	Yes	Specifies the value of the mantissa. If this parameter is not specified, the default is 23. When the WIDTH_EXP parameter is 8 and the floating-point format is single-precision, the WIDTH_MAN parameter value must be 23. Otherwise, the value of the WIDTH_MAN parameter must be a minimum of 31. The value of the WIDTH_MAN parameter must be greater than the value of the WIDTH_EXP parameter. The sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
PIPELINE	Integer	Yes	Specifies the amount of latency in clock cycles used in the ALTFP_INV megafunction. Create the ALTFP_INV megafunction with the MegaWizard Plug-In Manager to calculate the value for this parameter.
ROUNDING	String	No	Specifies the rounding mode. The default value is TO_NEAREST. Other rounding modes are not supported.

<code>clk_en</code>	No	Clock enable. When the <code>clk_en</code> port is asserted high, an inversion value operation takes place. When signal is asserted low, no operation occurs and the outputs remain unchanged.
<code>clock</code>	Yes	Clock input to the IP core.
<code>data[]</code>	Yes	Floating-point input data. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of the sign bit, exponent bits, and mantissa bits.

Table 11-6: ALTFP_INV_SQRT IP Core Output Signals

Port Name	Required	Description
<code>result[]</code>	Yes	The floating-point inverse result of the value at the <code>data[]</code> input port. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. The size of this port is the total width of the sign bit, exponent bits, and mantissa bits.
<code>zero</code>	No	Zero exception output. Asserted when the value at the <code>result[]</code> port is a zero.
<code>division_by_zero</code>	No	Division-by-zero exception output. Asserted when the denominator input is a zero.
<code>nan</code>	No	NaN exception output. Asserted when an invalid inversion of square root occurs, such as the square root of a negative number. In this case, a NaN value is output to the <code>result[]</code> output port. Any operation involving a NaN will also produce a NaN.

Parameters

Table 11-7: ALTFP_INV_SQRT Megafunction Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2^{(WIDTH_EXP - 1)} - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of the WIDTH_EXP parameter must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of the WIDTH_EXP parameter must be less than the value of the WIDTH_MAN parameter, and the sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
WIDTH_MAN	Integer	Yes	Specifies the value of the mantissa. If this parameter is not specified, the default is 23. When the WIDTH_EXP parameter is 8 and the floating-point format is single-precision, the WIDTH_MAN parameter value must be 23. Otherwise, the value of the WIDTH_MAN parameter must be a minimum of 31. The value of the WIDTH_MAN parameter must be greater than the value of the WIDTH_EXP parameter. The sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
PIPELINE	Integer	Yes	Specifies the amount of latency, expressed in clock cycles, used in the ALTFP_INV_SQRT megafunction. Create the ALTFP_INV_SQRT megafunction with the MegaWizard Plug-In Manager to calculate the value for this parameter.
ROUNDING	String	No	Specifies the rounding mode. The default value is TO_NEAREST. Other rounding modes are not supported.

You can use the ports and parameters available to customize the ALTFP_LOG IP core according to your application.

ALTFP_LOG Features

The ALTFP_LOG IP core offers the following features:

- Natural logarithm functions.
- Optional exception handling output ports such as `zero` and `nan`.

Output Latency

The output latency options for the ALTFP_LOG megafunction differs depending on the precision selected, the width of the mantissa, or both.

Table 12-1: Latency Options for Each Precision Format

Precision	Mantissa Width	Latency (in clock cycles)
Single	23	21
Double	52	34
Single Extended	31–36	25
	37–42	28
	43–48	31
	49–52	34

ALTFP_LOG Truth Table

This table lists the truth table for the natural logarithm operation.

Table 12-2: Truth Table for Natural Logarithm Operations

DATA[]	SIGN BIT	RESULT[]	Zero	NaN
Normal	0	Normal	0	0
Normal	1	NaN ⁽⁶⁾	0	1
1 ⁽⁷⁾	0	Zero	1	0
Denormal ⁽⁸⁾	0	Negative Infinity	0	0
Zero ⁽⁹⁾	0/1	Negative Infinity	0	0
Infinity	0	Positive Infinity	1	0
NaN	X	NaN	0	1

ALTFP_LOG Resource Utilization and Performance

This table lists the resource utilization and performance information for the ALTFP_LOG IP core. The information was derived using the Quartus II software version 10.0.

Table 12-3: ALTFP_LOG Resource Utilization and Performance for Stratix IV Devices

Device Family	Precision	Output Latency	Logic usage				f _{MAX} (MHz)
			Adaptive Look-Up Tables (ALUTs)	Dedicated Logic Registers (DLRs)	Adaptive Logic Modules (ALMs)	18-Bit DSP	
Stratix IV	Single	21	1,950	1,864	1,378	8	385
	Double	34	5,451	6,031	4,151	64	211

ALTFP_LOG Design Example: Natural Logarithm of Single-Precision Format Numbers

This design example uses the ALTFP_LOG IP core to compute the natural logarithm of single-precision format numbers. This example uses the parameter editor GUI to define the core.

⁽⁶⁾ The natural logarithm of a negative value is invalid. Therefore, the output produced is a NaN.

⁽⁷⁾ The “1” in this case is equivalent to $\ln 1$.

⁽⁸⁾ The value of positive denormalized numbers is a value that approximates zero, and the output produced is a negative infinity number.

⁽⁹⁾ The zero in this case represents zero special case of the IEEE standard. It is not equivalent to $\ln 0$, but instead approximates to it.

ALTFP_LOG Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

These figures show the expected simulation results in the ModelSim-Altera software.

Figure 12-1: ALTFP_LOG ModelSim Simulation Waveform (Input Data)

Figure 12-2: ALTFP_LOG ModelSim Simulation Waveform (Output Data)

This design example includes the input of special cases to show the exception handling of the IP core, such as the smallest valid input and the input value of “1”.

In this example, the output delay is set to 21 clock cycles. Therefore, the result is only shown at the output port after the 21st clock cycle at 102.5 ns.

Table 12-4: Summary of Input Values and Corresponding Outputs

This table lists the inputs and corresponding outputs obtained from the simulation in the waveforms.

Time	Event
0 ns, start-up	data[] value: 0000 0000h Output value: An undefined value is seen on the <code>result[]</code> port, which is ignored. All values seen on the output port before the 21st clock cycle are merely due to the behavior of the system during start-up and should be disregarded.

Time	Event
102.5 ns	Output value: FF80 0000h The natural logarithm of zero is negative infinity.
5 ns	data[] value: 8000 0000h This is a negative number.
107.5 ns	Output value: FFC0 0000h Exception handling ports: nan asserts The natural logarithm of a negative value is invalid. Therefore, the output produced is a NaN.
30 ns	data[] value: 0040 0000h The is a denormal value.
132.5 ns	Output value: FF80 0000h As denormal numbers are not supported, the input is forced to zero before going through the logarithm function. The natural logarithm of zero is negative infinity.
45 ns	data[] value: 0080 0000h This is the smallest valid input. All the input bits are 0 except the LSB of the exponent field.
147.5 ns	Output value: C2AE AC50h
60 ns	data[] value: 3F80 0000h The input value 3F80 0000h is equivalent to the actual value, $1.0 \times 2^0 = 1$.
152.5 ns	Output value: 0000 0000h Exception handling ports: zero asserts Since $\ln 1$ results in zero, it produces an output of zero.

Signals

Figure 12-3: ALTFP_LOG Signals

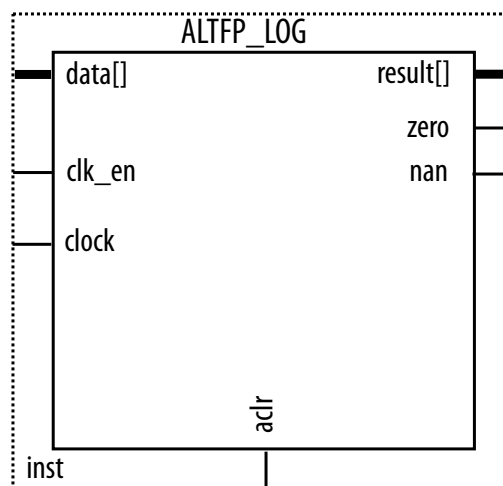

Table 12-5: ALTFP_LOG IP Core Input Signals

Port Name	Required	Description
<code>aclr</code>	No	Asynchronous clear. When the <code>aclr</code> port is asserted high, the function is asynchronously cleared.
<code>clk_en</code>	No	<p>Clock enable. When the <code>clk_en</code> port is asserted high, a natural logarithm operation takes place. When signal is asserted low, no operation occurs and the outputs remain unchanged.</p> <p>Deasserting <code>clk_en</code> halts operation until it is asserted again. Assert the <code>clk_en</code> signal for the number of clock cycles equivalent to the required output latency (<code>PIPELINE</code> parameter value) for the results to be shown at the output.</p>
<code>clock</code>	Yes	Clock input to the IP core.
<code>data[]</code>	Yes	<p>Floating-point input data. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of the sign bit, exponent bits, and mantissa bits.</p> <p>For single precision, the width is fixed to 32 bits. For double precision, the width is fixed to 64 bits. For single extended precision, you can choose a width in the range from 43 to 64 bits.</p>

Table 12-6: ALTFP_LOG IP Core Output Signals

Port Name	Required	Description
<code>result[]</code>	Yes	The natural logarithm of the value on input data. The natural logarithm of the <code>data[]</code> input port, shown in floating-point format. The widths of the <code>result[]</code> output port and <code>data[]</code> input port are the same.

Port Name	Required	Description
zero	No	Zero exception output. Asserted when the exponent and mantissa of the output port are zero. This occurs when the actual input value is 1 because $\ln 1 = 0$.
nan	No	NaN exception output. Asserted when the exponent and mantissa of the output port are all 1's and non-zero, respectively. This occurs when the input is a negative number or NaN.

Parameters

Table 12-7: ALTFP_LOG Megafunction Parameters

Parameter Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2^{(WIDTH_EXP - 1)} - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of the WIDTH_EXP parameter must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of the WIDTH_EXP parameter must be less than the value of the WIDTH_MAN parameter, and the sum of the WIDTH_EXP and WIDTH_MAN parameters must be less than 64.
WIDTH_MAN	Integer	Yes	Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. The value of WIDTH_MAN must be 23 for the single-precision format, and 52 for the double-precision format. For the single-extended precision format, the valid value ranges from 31 to 52. The value of WIDTH_MAN must be greater than the value of WIDTH_EXP, and the sum of WIDTH_EXP and WIDTH_MAN must be less than 64.
PIPELINE	Integer	Yes	Specifies the amount of latency in clock cycles used in the ALTFP_LOG megafunction. Create the ALTFP_LOG megafunction with the MegaWizard Plug-In Manager to calculate the value for this parameter.

ALTFP_ABS Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

Figure 15-1: ALTFP_ABS Simulation Waveform

This design example produces a floating-point absolute value function for the multiplication results of single-precision format numbers. All the optional input ports (`clk_en` and `aclr`) and optional output ports (`overflow`, `underflow`, `zero`, `division_by_zero`, and `nan`) are enabled.

In this example, the latency of the multiplier is set to five clock cycles, while none is being set for the absolute value function. Thus, the absolute value result only appears at the `result[]` port five cycles after the input values are captured on the input ports.

The `dataa[]` and `datab[]` values in the simulation waveform above portray the two input values that are being fed to the multiplier. The value in the `result[]` port depicts the multiplication result that has gone through the absolute value operation.

This table lists the inputs and corresponding outputs obtained from the simulation.

Table 15-2: Summary of Input Values and Corresponding Outputs

Time	Event
0 ns, start-up	<p><code>dataa[]</code> value: C080 0000h</p> <p><code>datab[]</code> value: 4000 0000h</p> <p>Output value: All values seen on the output port before the 5th clock cycle are merely due to the behavior of the system during start-up and should be disregarded.</p>
22.5 ns	<p>Output value: 4100 0000h</p> <p>The multiplication of a negative number with a positive number results in a negative number. The absolute value of the result is reflected on the <code>result[]</code> port.</p>
20 ns	<p><code>dataa[]</code> value: 579D F479h</p> <p><code>datab[]</code> value: 7F80 0000h</p> <p>The value of <code>dataa[]</code> is normal while the value of <code>datab[]</code> is infinity.</p>
42.5 ns	<p>Output value: 7F80 0000h</p> <p>Exception handling ports: <code>overflow</code> asserts</p> <p>The multiplication of a normal value with infinity results in infinity and sets the <code>overflow</code> port in the multiplier. The absolute value of the output is infinity and the <code>overflow</code> port is also set as this assertion of the port is being carried through from the corresponding <code>overflow</code> port in the multiplier.</p>

ALTFP_ABS Signals

Figure 15-2: ALTFP_ABS Signals

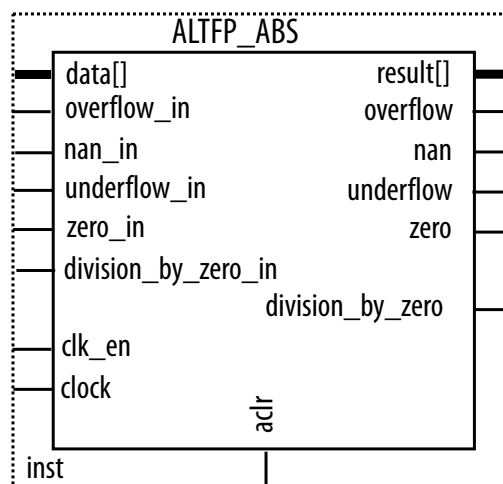

Table 15-3: ALTFP_ABS Input Signals

Port Name	Required	Description
aclr	No	Asynchronous clear. When the <code>aclr</code> port is asserted high, the function is asynchronously cleared.
clk_en	No	Clock enable. When the <code>clk_en</code> port is asserted high, an absolute value operation takes place. When the signal is asserted low, no operation occurs and the outputs remain unchanged.
clock	Yes	Clock input to the IP core.
data[]	Yes	Floating-point input data. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.
zero_in	No	Zero exception input. Carry-through exception input port from other floating-point modules.
nan_in	No	NaN exception input. Carry-through exception input port from other floating-point modules.
overflow_in	No	Overflow exception input. Carry-through exception input port from other floating-point modules.
underflow_in	No	Underflow exception input. Carry-through exception input port from other floating-point modules.
division_by_zero_in	No	Division-by-zero exception input. Carry-through exception input port from other floating-point modules.

Table 15-4: ALTFP_ABS Output Signals

Port Name	Required	Description
result[]	Yes	The absolute value result of the input data. The size of this port corresponds to the size of the input <code>data[]</code> port.
zero	No	Zero exception output carried from the input. Asserted if the corresponding carry-through port from the input is asserted.
nan	No	NaN output carried from the input. Asserted if the corresponding carry-through port from the input is asserted.
overflow	No	Overflow exception output carried from the input. Asserted if the corresponding carry-through port from the input is asserted.
underflow	No	Underflow exception output carried from the input. Asserted if the corresponding carry-through port from the input is asserted.
division_by_zero	No	Division-by-zero exception output carried from the input. Asserted if the corresponding carry-through port from the input is asserted.

ALTFP_ABS Parameters

Table 15-5: ALTFP_ABS Parameters

Port Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to 2 ($\text{WIDTH_EXP} - 1$) - 1, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of <code>WIDTH_EXP</code> must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of <code>WIDTH_EXP</code> must be less than the value of <code>WIDTH_MAN</code> , and the sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64.

Port Name	Type	Required	Description
WIDTH_MAN	Integer	Yes	Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. When WIDTH_EXP is 8 and the floating-point format is single-precision, the WIDTH_MAN value must be 23. Otherwise, the value of WIDTH_MAN must be a minimum of 31. The value of WIDTH_MAN must be greater than the value of WIDTH_EXP, and the sum of WIDTH_EXP and WIDTH_MAN must be less than 64.
PIPELINE	Integer	Yes	Specifies the amount of latency, expressed in clock cycles, used in the ALTFP_ABS IP core. Create the ALTFP_ABS IP core with the parameter editor to calculate the value for this parameter.

ALTFP_COMPARE Features

The ALTFP_COMPARE IP core offers the following features:

- Comparison functions between two inputs.
- Seven status output ports:
 - `aeb` (input A is equal to input B).
 - `aneb` (input A is not equal to input B).
 - `agb` (input A is greater than input B).
 - `ageb` (input A is greater than or equal to input B).
 - `alb` (input A is less than input B).
 - `aleb` (input A is less than or equal to input B).
 - `unordered` (used as an output to flag if one or both input ports are NaN).

ALTFP_COMPARE Output Latency

The output latency options for the ALTFP_COMPARE IP core are the same for all three precision formats—single, double, and single-extended. The options available are 1, 2, and 3 clock cycles.

ALTFP_COMPARE Resource Utilization and Performance

This table lists the resource utilization and performance information for the ALTFP_COMPARE IP core. The information was derived using the Quartus II software version 10.0.

ALTFP_COMPARE Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

This figure shows the expected simulation results in the ModelSim-Altera software.

Figure 16-1: ALTFP_COMPARE Simulation Waveform

This design example implements a floating-point comparator for single-precision numbers. Both optional input ports (clk_en and ackr) and all seven output ports (ageb, aeb, agb, aneb, alb, aleb, and unordered) are enabled.

The chosen output latency is 3. Therefore, the comparison operation generates the output result 3 clock cycles later.

This table lists the inputs and corresponding outputs obtained from the simulation in the waveform.

Table 16-2: Summary of Input Values and Corresponding Outputs

Time	Event
0 ns, start-up	<p>dataa[] value: 619B CE11h</p> <p>datab[] value: 9106 CA22h</p> <p>Output value: An undefined value is seen on the <code>result[]</code> port, which is ignored. All values seen on the output port before the 3rd clock cycle are merely due to the behavior of the system during start-up and should be disregarded.</p>
25 ns	Output ports: <code>ageb</code> , <code>aneb</code> , and <code>agb</code> assert
350 ns	<p>dataa[] value: 0060 0000h</p> <p>datab[] value: 0070 0000h</p> <p>Both input values are denormal numbers.</p>
375 ns	<p>Output ports: <code>aeb</code>, <code>ageb</code>, and <code>aleb</code> assert</p> <p>Denormal inputs are not supported and are forced to zero before comparison takes place, which results in the <code>dataa[]</code> value being equal to <code>datab[]</code>.</p>
460 ns	The <code>aclr</code> signal is set for 1 clock cycle.
495.5 ns	The comparisons of subsequent data inputs are performed 3 clock cycles after the <code>aclr</code> signal deasserts.

ALTFP_COMPARE Signals

Figure 16-2: ALTFP_COMPARE Signals

Table 16-3: ALTFP_COMPARE Input Signals

Port Name	Required	Description
aclr	No	Asynchronous clear. The source is asynchronously reset when asserted high.
clk_en	No	Clock enable. When this port is asserted high, a compare operation takes place. When signal is asserted low, no operation occurs and the outputs remain unchanged.
clock	Yes	Clock input to the IP core.
dataa[]	Yes	Data input. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.
datab[]	Yes	Data input. The MSB is the sign bit, the next MSBs are the exponent, and the LSBs are the mantissa. This input port size is the total width of sign bit, exponent bits, and mantissa bits.

Table 16-4: ALTFP_COMPARE Output Signals

Port Name	Required	Description
aeb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port equals the value of the datab[] port.
agb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port is greater than the value of the datab[] port.
ageb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port is greater than or equal to the value of the datab[] port.
alb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port is less than the value of the datab[] port.
aleb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port is less than or equal to the value of the datab[] port.
aneb	Yes	Output port for the comparator. Asserted if the value of the dataa[] port is not equal to the value of the datab[] port.
unordered	Yes	Output port for the comparator. Asserted when either the dataa[] port and the datab[] port is set to NaN, or if both the dataa[] port and the datab[] port are set to NaN.

ALTFP_COMPARE Parameters

Table 16-5: ALTFP_COMPARE Parameters

Port Name	Type	Required	Description
WIDTH_EXP	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to 2 ($WIDTH_EXP - 1$) - 1, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of <code>WIDTH_EXP</code> must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of <code>WIDTH_EXP</code> must be less than the value of <code>WIDTH_MAN</code> , and the sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64.
WIDTH_MAN	Integer	Yes	Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. When <code>WIDTH_EXP</code> is 8 and the floating-point format is single-precision, the <code>WIDTH_MAN</code> value must be 23. Otherwise, the value of <code>WIDTH_MAN</code> must be a minimum of 31. The value of <code>WIDTH_MAN</code> must be greater than the value of <code>WIDTH_EXP</code> , and the sum of <code>WIDTH_EXP</code> and <code>WIDTH_MAN</code> must be less than 64.
PIPELINE	Integer	Yes	Specifies the latency in clock cycles used in the ALTFP_COMPARE IP core. The pipeline values are 1, 2, and 3 latency in clock cycles.

ALTFP_CONVERT Features

The ALTFP_CONVERT IP core offers the following features:

- Conversion functions for the following formats:
 - Integer-to-Float
 - Float-to-Integer
 - Float-to-Float
 - Fixed-to-Float
 - Float-to-Fixed
- Support for signed and unsigned integer
- Optional exception handling output ports such as `overflow`, `underflow`, and `nan`

Table 17-1: Supported Operations and Exception Ports

Operation	Supported Exception Ports
Integer-to-Float	Not supported
Float-to-Integer	<code>overflow</code> , <code>underflow</code> , and <code>nan</code>
Float-to-Float	<code>overflow</code> , <code>underflow</code> , and <code>nan</code>
Fixed-to-Float	Not supported
Float-to-Fixed	<code>overflow</code> , <code>underflow</code> , and <code>nan</code>

ALTFP_CONVERT Conversion Operations

This table lists the features of each conversion operation.

ALTFP_CONVERT Design Example: Understanding the Simulation Results

The simulation waveform in this design example is not shown in its entirety. Run the design example files in the ModelSim-Altera software to see the complete simulation waveforms.

This figure shows the expected simulation results in the ModelSim-Altera software.

Figure 17-1: ALTFP_CONVERT Simulation Waveform

This design example implements a float-to-integer converter for converting double-precision floating-point format numbers to 64-bit integers. In this operation, the optional exception ports of `overflow`, `underflow`, and `nan` are available apart from the `result[]` port.

The latency for the float-to-integer operation is six clock cycles. Therefore, each conversion generates the output result six clock cycles after receiving the input value.

This table lists the inputs and corresponding outputs obtained from the simulation in the waveform.

Table 17-5: Summary of Input Values and Corresponding Outputs

Time	Event
0 ns, start-up	<p>dataa[] value: C394 AD22 761B 9EE5h</p> <p>Output value: The <code>result[]</code> port displays 0 regardless of what the input value is. This value seen on the output port before the 6th clock cycle is merely due to the behavior of the system during start-up and should be disregarded.</p>
55 ns	Output value: FAD4 B762 7918 46C0h
150 ns	<p>dataa[] value: 000F 0000 5555 1111h</p> <p>This value is a denormal number.</p>
205 ns	Denormal inputs are not supported and are forced to zero before conversion takes place.
300 ns	dataa[] value: 5706 40CF OEC6 1176h
355 ns	<p>Output value: 7FFF FFFF FFFF FFFFh</p> <p>Exception handling ports: <code>overflow</code> asserts.</p> <p>The <code>overflow</code> flag is triggered because the width of the resulting integer is more than the maximum width allowed, and the value seen on the <code>result[]</code> port is the standard value used to represent a positive overflow number.</p>
350 ns	dataa[] value: C728 3147 8444 1F75h
405 ns	<p>Output value: 8000 0000 0000 0000h</p> <p>Exception handling ports: <code>overflow</code> remains asserted.</p> <p>This is a standard value to represent a negative overflow number.</p>
400 ns	dataa[] value: 145A 257C 895A B309h
455 ns	<p>Output value: 0000 0000h</p> <p>Exception handling ports: <code>underflow</code> asserts.</p> <p>The input value triggers the <code>underflow</code> port because the exponent of the input value is less than the exponent bias of 1023.</p>
500 ns	<p>dataa[] value: FFFF 0000 DDDD 5555h</p> <p>This value is a NaN.</p>
555 ns	<p>Output value: 0000 0000h</p> <p>Exception handling ports: <code>nan</code> asserts.</p>

ALTFP_CONVERT Signals

Figure 17-2: ALTFP_CONVERT Signals

Table 17-6: ALTFP_CONVERT Input Signals

Port Name	Required	Description
clock	Yes	The clock input to the ALTFP_CONVERT IP core.
clk_en	No	Clock enable that allows conversions to take place when asserted high. When asserted low, no operation occurs and the outputs are unchanged.
aclr	No	Asynchronous clear. The source is asynchronously reset when the <code>aclr</code> signal is asserted high.
dataa[]	Yes	<p>Data input. The size of this input port depends on the <code>WIDTH_DATA</code> parameter value.</p> <p>If the operation mode value is <code>INT2FLOAT</code> or <code>FIXED2FLOAT</code>, the data on the input bus is an integer.</p> <p>If the operation mode value is <code>FLOAT2INT</code> or <code>FLOAT2FIXED</code>, the input bus is the IEEE floating-point representation. In the single-precision format, the input bus width value is 32. In the double-precision format, the input bus width value is 64.</p> <p>In the single-extended precision format, the input bus range is from 43 to 64.</p> <p>If the operation mode value is <code>FLOAT2FLOAT</code>, the input bus value is the IEEE floating-point representation. In the single-precision format, the input bus width value is 32. In the double-precision format, the input bus width value is 64. In the single-extended precision format, the input bus range is from 43 to 64.</p>

Table 17-7: ALTFP_CONVERT Output Signals

Port Name	Required	Description
result[]	Yes	<p>Output for the floating-point converter. The size of this output port depends on the <code>WIDTH_RESULT</code> parameter value.</p> <p>If the operation mode value is <code>FLOAT2INT</code> or <code>FLOAT2FIXED</code>, the output bus is an IEEE floating-point representation.</p> <p>If the operation mode is <code>FLOAT2INT</code>, the output bus is an integer representation. If the selected precision is the single-precision format, the output bus width value is 32. If the selected precision is the double-precision format, the output bus width value is 64. If the selected precision is the single-extended precision format, the input bus range is from 43 to 64.</p> <p>If the operation mode value is <code>FLOAT2FLOAT</code>, the output bus is an IEEE floating-point representation. If the selected precision is the single-precision format, the output bus is in the 64-bit double-precision format. If the selected precision is the double-precision format, the output bus is in the 32-bit single-precision format. If the selected precision is the single-extended precision format, the output bus ranges from 43 to 64.</p>
overflow	No	<p>Optional overflow exception output. This port is available only when the operation mode values are <code>FLOAT2FIXED</code>, <code>FLOAT2INT</code>, or <code>FLOAT2FLOAT</code>.</p> <p>Asserted when the result of the conversion (after rounding), exceeds the maximum width of the <code>result[]</code> port, or when the <code>dataa[]</code> input is infinity.</p>
underflow	No	<p>Optional underflow exception output. This port is available only when the operation mode values are <code>FLOAT2FIXED</code>, <code>FLOAT2INT</code>, or <code>FLOAT2FLOAT</code>.</p> <p>Asserted when the result of the conversion, after rounding, is fractional.</p> <p>In <code>FLOAT2INT</code> operations, this port is asserted when the exponent value of the floating-point input is smaller than the exponent bias.</p> <p>In <code>FLOAT2FLOAT</code> operations, this port is asserted when the floating-point input has a value smaller than the lowest exponent limit of the target floating-point format.</p>
nan	No	<p>Optional NaN exception output. This port is available only when the operation mode values are <code>FLOAT2INT</code>, <code>FLOAT2FLOAT</code>, or <code>FLOAT2FIXED</code>.</p> <p>Asserted when the input port is a NaN representation.</p> <p>If the operation mode value is <code>FLOAT2INT</code> or <code>FLOAT2FIXED</code>, the <code>result[]</code> port is set to zero.</p> <p>If the operation mode value is <code>FLOAT2FLOAT</code>, the <code>result[]</code> port is set to a NaN representation.</p>

ALTFP_CONVERT Parameters

Table 17-8: ALTFP_CONVERT Parameters

Port Name	Type	Required	Description
WIDTH_EXP_INPUT	Integer	Yes	Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to $2(\text{WIDTH_EXP} - 1) - 1$, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of WIDTH_EXP_INPUT must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of WIDTH_EXP_INPUT must be less than the value of WIDTH_MAN_INPUT, and the sum of WIDTH_EXP_INPUT and WIDTH_MAN_INPUT must be less than 64. These settings apply only to the FLOAT2FIXED, FLOAT2INT, and FLOAT2FLOAT operation modes.
WIDTH_MAN_INPUT	Integer	Yes	Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. When WIDTH_EXP_INPUT is 8 and the floating-point format is single-precision, the WIDTH_MAN_INPUT value must be 23. Otherwise, the value of WIDTH_MAN_INPUT must be a minimum of 31. The value of WIDTH_MAN_INPUT must be greater than the value of WIDTH_EXP_INPUT, and the sum of WIDTH_EXP_INPUT and WIDTH_MAN_INPUT must be less than 64. These settings apply only to the FLOAT2FIXED, FLOAT2INT, and FLOAT2FLOAT operation modes.
WIDTH_INT	Integer	Yes	Specifies the integer width. If the operation is FIXED2FLOAT or INT2FLOAT, this parameter defines the integer width on the input side. If the operation is FLOAT2INT or FLOAT2FIXED, this parameter defines the result width on the output side. The available settings are 32 bits, 64 bits or n bits. For n bits settings, the range is from 4 bits to 64 bits. If unspecified, the default setting for WIDTH_INT is 32 bits.

Port Name	Type	Required	Description
WIDTH_DATA	Integer	Yes	<p>Specifies the input data width.</p> <p>If the operation is INT2FLOAT, the WIDTH_DATA is also WIDTH_INT.</p> <p>If the operation is FIXED2FLOAT, the data width value is WIDTH_INT + fractional width.</p> <p>If the operation is FLOAT2FIXED, FLOAT2INT or FLOAT2FLOAT, the data width value is WIDTH_EXP_INPUT + WIDTH_MAN_INPUT + 1.</p> <p>The available settings are 32 bits, 64 bits or n bits. For n bits settings, the range is from 4 bits to 64 bits.</p> <p>If unspecified, the default setting for WIDTH_DATA is 32 bits.</p>
WIDTH_EXP_OUTPUT	Integer	Yes	<p>Specifies the precision of the exponent. If this parameter is not specified, the default is 8. The bias of the exponent is always set to 2 (WIDTH_EXP - 1) - 1, that is, 127 for the single-precision format and 1023 for the double-precision format. The value of WIDTH_EXP_OUTPUT must be 8 for the single-precision format, 11 for the double-precision format, and a minimum of 11 for the single-extended precision format. The value of WIDTH_EXP_OUTPUT must be less than the value of WIDTH_MAN_OUTPUT, and the sum of WIDTH_EXP_OUTPUT and WIDTH_MAN_OUTPUT must be less than 64. These settings apply only to the FLOAT2FIXED, FLOAT2INT, and FLOAT2FLOAT operation modes.</p>
WIDTH_MAN_OUTPUT	Integer	Yes	<p>Specifies the precision of the mantissa. If this parameter is not specified, the default is 23. When WIDTH_EXP_OUTPUT is 8 and the floating point format is single-precision, the WIDTH_MAN_OUTPUT value must be 23. Otherwise, the value of WIDTH_MAN_OUTPUT must be a minimum of 31. The value of WIDTH_MAN_OUTPUT must be greater than the value of WIDTH_EXP_OUTPUT, and the sum of WIDTH_EXP_OUTPUT and WIDTH_MAN_OUTPUT must be less than 64. These settings apply only to the FLOAT2FIXED, FLOAT2INT, and FLOAT2FLOAT operation modes.</p>
WIDTH_RESULT	Integer	Yes	<p>Specifies the width of the output result. In an INT2FLOAT, FLOAT2FLOAT, or FIXED2FLOAT operation, the result width is WIDTH_EXP_OUTPUT + WIDTH_MAN_OUTPUT + 1. In a FLOAT2INT operation, the result width is the value of the WIDTH_INT parameter.</p> <p>In a FLOAT2FIXED operation, this parameter is the result width.</p> <p>The available settings are 32 bits, 64 bits or n bits. For n bits settings, the range is from 4 bits to 64 bits.</p>

Port Name	Type	Required	Description
ROUNDING	Integer	Yes	Specifies the rounding mode. The default value is TO_NEAREST. Other modes are not supported.
OPERATION	Integer	Yes	<p>Specifies the operating mode. Values are INT2FLOAT, FLOAT2INT, FLOAT2FLOAT, FLOAT2FIXED, and FIXED2FLOAT. If this parameter is not specified, the default value is INT2FLOAT.</p> <p>When set to INT2FLOAT, the conversion of an integer input to an IEEE floating-point representation output takes place.</p> <p>When set to FLOAT2INT, the conversion of an IEEE floating-point representation input to an integer output takes place.</p> <p>When set to FLOAT2FLOAT, the conversion between IEEE floating-point representations input and output takes place.</p> <p>When set to FIXED2FLOAT, the conversion of a fixed point input to an IEEE floating-point representation output takes place.</p> <p>When set to FLOAT2FIXED, the IEEE floating-point input conversion to fixed point representation output takes place.</p>

ALTERA_FP_FUNCTIONS Output Latency

If you require a specific latency, follow these steps:

1. In the ALTERA_FP_FUNCTIONS parameter editor, click the **Basic** tab.
2. Under the Performance category, in the **Goal** option, select **latency**.
3. In the **Target** field, set your desired latency (cycles).
4. Then, click **Check Performance**.

ALTERA_FP_FUNCTIONS Target Frequency

If you require a specific frequency, follow these steps:

1. In the ALTERA_FP_FUNCTIONS parameter editor, click **Basic** tab.
2. Under the Performance category, in the **Goal** option, select **frequency**.
3. In the **Target** field, set your desired frequency (MHz).
4. The IP core reports the latency for the instance that it will generate in the Report category.

Note: You must verify the frequency by running the TimeQuest Timing Analyzer.

ALTERA_FP_FUNCTIONS Combined Target

If you require a combined target of latency and frequency, follow these steps:

1. In the ALTERA_FP_FUNCTIONS parameter editor, click the **Basic** tab.
2. Under the Performance category, in the **Goal** option, select **Combined**.
3. In the **Target** field, set your desired frequency (MHz).
4. In the **Target** field, set your desired latency (cycles).
5. Then, click **Finish**.

ALTERA_FP_FUNCTIONS Resource Utilization and Performance

These tables list the resource utilization and performance information for the ALTERA_FP_FUNCTIONS IP core. The information was derived using the Quartus II software version 14.1. The frequency target was set to 200 MHz.

Table 18-2: Arithmetic

ALTERA_FP_FUNCTIONS Signals

Figure 18-1: ALTERA_FP_FUNCTIONS Signals

- 1) The floating point and fixed point data widths determine the port width of this port.
- 2) This port is not relevant for convert and square root functions.

Table 18-6: ALTERA_FP_FUNCTIONS Input Signals

Port Name	Required	Description
clk	Yes	All input signals must be synchronous to this clock.
areset	Yes	Asynchronous active-high reset. Deassert this signal synchronously to the input clock to avoid metastability issues.
en	No	Global enable signal. This signal is optional.
a	Yes	Data input signal.
b	Yes	Data input signal (where applicable).
s	Yes	Select port for Add/Sub function.
c	Yes	Data port for integer exponent port for LDExp function.

Table 18-7: ALTERA_FP_FUNCTIONS Output Signals

Port Name	Required	Description
q	Yes	Data output signal.

ALTERA_FP_FUNCTIONS Parameters

These tables list the ALTERA_FP_FUNCTIONS parameters.

Table 18-8: ALTERA_FP_FUNCTIONS Parameters: Functionality Tab

Category	Parameter	Values	Descriptions
Function	Family	All, Arithmetic, Comparisons, Conversions, Exp/Log/Pow, Roots, Trigonometry	Allows you to chose which functions will be displayed in the Function Name Parameter list
Function	Name	<ul style="list-style-type: none">• Add• Sub• Add/Sub• Multiply• Divide• Reciprocal• Absolute• Scalar Product• Square Root• Cube Root• Inverse Square Root• Fixed to Floating Point• Floating Point to Fixed	Allows you to choose your desired function. NB, this parameter will only display the options you have selected from the Family Parameter

Category	Parameter	Values	Descriptions
Function	Name	<ul style="list-style-type: none"> Width Conversions Min Max Less than (or equal) Greater than (or equal) (Not) Equal Power Exponential (Base 2, 10, e) Log (Base 2, 10, e) Log (1+x) LDExp Sin Cos Tan Arcsin Arccos Arctan 	Allows you to choose your desired function. NB, this parameter will only display the options you have selected from the Family Parameter
Floating Point Data	Format	Single, Double, Custom	Allows you to choose the floating point format of the data values. The default value is single.
	Exponent	5 to 8	Allows you to specify the width of the exponent. This parameter is only available when the Format parameter is set to custom. The default value is 8.
	Mantissa	10 to 52	Allows you to specify the width of the mantissa. This parameter is only available when the Format parameter is set to custom. The default value is 23.
	Exponent Width	1 to Floating Point Data Exponent Width	Allows you to specify the width of the separate Exponent port for the LDExp function

Category	Parameter	Values	Descriptions
Fixed Point Data	Width	16 to 128	The bit width of the fixed point data port. This parameter is only available when the Name parameter is set to Convert.
	Fraction	0 to Fixed Point Data Width	The bit width of the fraction. This parameter is only available when the Name parameter is set to Convert.
	Sign	Signed, Unsigned	Choose if the fixed point data is signed or unsigned. This parameter is only available when the Name parameter is set to Convert. The default value is signed.
Rounding	Mode	<ul style="list-style-type: none">• nearest with tie breaking to even• toward zero• nearest with tie breaking away from zero	The rounding mode. The nearest with tie breaking away from zero and toward zero values are only available when you use arithmetic functions
	Relax rounding to round up or down to reduce resource usage	Turn on, Turn Off	Choose if the nearest rounding mode should be relaxed to faithful rounding, where the result may be rounded up or down, to reduce resource usage. Only available for arithmetic functions
Ports	Generate Enable Port	Turn on, Turn Off	Choose if the ALTERA_FP_FUNCTION IP core should have an enable signal.

Table 18-9: ALTERA_FP_FUNCTIONS Parameters: Performance Tab

Category	Parameter	Values	Descriptions
Target	Goal	<ul style="list-style-type: none"> Frequency Latency Combined 	If the Goal is the frequency, then the Target is the desired frequency in MHz. This, together with the target device family, will determine the amount of pipelining. If the Goal is latency, then the Target is the desired latency. If the Goal is Combined then two Targets are displayed, one is the desired frequency in MHz, one is the target latency in cycles. When you set the Goal parameter to frequency, the default value is 200 MHz When you set the Goal parameter to latency, the default value is 2.
	Target	Any Positive Integer	
	Enable Hard Floating Point	Turn on, Turn Off	Allows you to chose whether Hard Floating Point DSP Blocks will be used to implement the function on devices with those features
